

R6500 Microcomputer System APPLICATION NOTE

Using R65XX Family Peripheral Devices With The Z80 CPU

INTRODUCTION

Many microprocessor system designs using the Z80 Central Processor Unit could be greatly improved by using the Rockwell R65XX series peripheral devices. Members of this family — such as the R6522 Versatile Interface Adapter, the R6545 CRT Controller, the R6520 Peripheral Interface Adapter, and the R6551 ACIA — may prove to be both cost-effective and versatile in Z80 based designs. This application note presents one possible approach to the interfacing of the Z80 bus to the R65XX, which will allow the system designer greater freedom to select the best possible compliment of I/O designs for use in a Z80 system.

TIMING DIFFERENCES

Some basic timing differences exist between the Z80 and the R65XX bus.

Z80 Timing

The Z80 I/O cycle timing diagrams are shown in Figure 1. Note that all data transfers are controlled by the ϕ_0 clock. A Z80 I/O cycle has four clock periods. During the first clock period, T1, the Port address is placed on the Address Bus and, for a write cycle, the processor places the output data on the Data Bus. During T2, the $\overline{\text{IORQ}}$ line is asserted, to indicate an I/O cycle is occurring, and either the $\overline{\text{RD}}$ or $\overline{\text{WR}}$ line is taken low, to indicate an input or output, respectively. The processor then automatically inserts a WAIT state, Tw. An additional WAIT cycle may be externally inserted by taking the WAIT line low during Tw. In this case, the next cycle will also be a WAIT state. During the final period, T3, the data is latched into the processor on a read cycle and $\overline{\text{IORQ}}$, $\overline{\text{RD}}$ or $\overline{\text{WR}}$ are released.

R65XX Timing

Figure 2 shows the R65XX timing diagram. All data transfers take place during a single cycle of the phase-two (ϕ_2) clock. During the first half of the cycle (ϕ_2 low), the address of the memory or peripheral is placed on the Address Bus and the $\text{R}/\overline{\text{W}}$ line is asserted. On the rising edge of ϕ_2 , the address and

$\text{R}/\overline{\text{W}}$ status are latched into the R65XX peripheral device. Then, during the ϕ_2 high period, the data is placed on the data bus by either the CPU or the peripheral, depending on the state of the $\text{R}/\overline{\text{W}}$ line. The data is latched on the falling edge of the ϕ_2 clock.

INTERFACE TIMING

Figure 3 shows the necessary timing relationships between the Z80 CPU and the R65XX peripheral series. It should be noted that the ϕ_2 clock is derived from the Z80 ϕ_0 clock by a divide-by-two function. In order to operate correctly, the ϕ_2 clock must be low at the start of a Z80 I/O cycle. The Z80 processor, however, does not always execute an even number of ϕ_0 cycles between I/O cycles. This may result in the generated ϕ_2 being out of phase by one-half of a cycle at the beginning of a Z80 I/O cycle. Figure 4 shows the relationships when ϕ_2 is high at the beginning of a Z80 I/O cycle. It is necessary to insert an additional WAIT state into the Z80 I/O cycle in order to delay the Z80 data transfer until ϕ_2 has the proper relationship.

The Circuit

Figure 5 shows a circuit which can be used to realize this interface. Note that this circuit can be built with only four Low Power Shottky TTL packages. The Z80 ϕ_0 clock is divided by two by the 74LS73. This output is then used as the ϕ_2 clock by the R65XX peripheral. It is also compared with ϕ_0 , $\overline{\text{IORQ}}$, and R65XX SELECT, to determine if a WAIT state is necessary. A WAIT state is generated for one ϕ_0 cycle by the second half of the 74LS73. The $\overline{\text{IORQ}}$ is delayed by half of the 74LS74 and gated with the R65XX SELECT to form the $\overline{\text{CS}}$ input. The $\overline{\text{WR}}$ signal is synchronized with ϕ_2 and used as the R65XX $\text{R}/\overline{\text{W}}$ input.

It should be noted that the output driving the WAIT input may need to be buffered with an open-collector driver if other system devices are to generate Z80 wait states.

In order to maintain speed compatibility, a Z80 CPU operating at 2-MHz can be used with 1-MHz R65XX parts, and a 4-MHz Z80 requires the use of 2-MHz R65XXA series parts.
