## USE IN LIFE SUPPORT MUST BE EXPRESSLY AUTHORIZED

SGS-THOMSON' PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF SGS-THOMSON Microelectronics. As used herein:

1. Life support devices to systems are devices or systems which, are intended for surgical implant into the body to support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

## SGS-THOMSON TELEPHONE SET: THE BROADEST PRODUCT RANGE

SGS-THOMSON has been designing and producing dedicated telephone set products since the first voice circuits were introduced in the 1970s. Today, at the beginning of the nineties, the company offers the widest telephone product range in the world and ships more than 50 million dedicated ICs per year, plus some ten million protection devices.
This comprehensive product family covers not just all the telephone functions, but the various national standards, too. A complete kit solution for a basic telephone - speech circuit, dialer and ringer - is available for each country. Moreover, thanks to families of pin-compatible devices it is easy to adapt a design to different standards.
In addition to the basic telephone kits SGS-THOMSON provides circuits designed to allow modular expansion, adding features such as loudspeaking or handsfree capability.
For the early nineties SGS-THOMSON is readying advanced telephone components using advanced mixed technologies. By the time you read this note samples may be available. Stay in touch with SGS-THOMSON to keep up to date with the state of the art.

MODULAR APPROACH. The SGS-THOMSON telephone product range includes a basic, telephone kit for each national standard plus add-on function ICs that turn a basic phone into a feature phone.

## INTRODUCTION

ADVANCED TECHNOLOGY. Using an advanced mixed technology SGS-THOMSON has already produced a custom single-chip telephone for a major telecom manufacturer.

## DIALER CIRCUITS

## DTMF GENERATOR FOR BINARY CODED HEXADECIMAL DATA

- GENERATES 16 STANDARD DTMF TONE PAIRS
■ USES LOW COST 3.579 MHz CRYSTAL
- DIRECT MICROPROCESSOR INTERFACE
- ACCEPTS 4 BIT DATA IN SERIAL OR PARALLEL FORMAT
- DATA IS STORED DURING TRANSMISSION PERIOD
- LOW HARMONIC DISTORTION
- HIGH GROUP PRE EMPHASIS
- LOW POWER CONSUMPTION IN STANDBY MODE
- PULL-UP TO V ${ }^{+}$ON ALL LOGIC INPUTS

## DESCRIPTION

This CMOS circuit is designed specifically to provide, with a minimum number of external components, a low cost DTMF dialer for microprocessor controlled telephone sets operating in accordance with existing standards. The 4 bits identifying the frequency pair to be generated may be supplied via either 5 connections between the EFG7189 and the microprocessor in parallel format or in serial format through 3 connections linking the EFG71891 to the microprocessor. This feature eliminates the necessity to simulate keyboard type inputs normally required by standard DTMF generators. Input data is stored on trailing edge of ISA signal. The tone pair selected by this code is generated while ISA remains low. With ISA high, the oscillator is inhibited and the device is in standby mode. SA pin is connected to $\checkmark$ while device is outputting any tone pair.

## PIN DESCRIPTION

| $\mathrm{N}^{\circ}$ | Name | Function | Description |
| :---: | :---: | :---: | :---: |
| $\begin{array}{r} 1 \\ 4 \\ \hline \end{array}$ | $\begin{aligned} & \hline \mathrm{V}^{+} \\ & \mathrm{V}^{-} \end{aligned}$ | Supply Voltage Supply Voltage | Positive Supply 0 V |
| $\begin{gathered} 11 \\ 10 \\ 9 \end{gathered}$ | $\begin{aligned} & \hline \mathrm{B} \\ & \mathrm{C} \\ & \mathrm{D} \end{aligned}$ | Logic Input Logic Input Logic Input | Parallel input for hexadecimal code allowing the selection of 2 frequencies constituting the DTMF signal (see attached table). |
| 12 | A | Logic Input | Serial or Parallel Input for Hexadecimal Code |
| 13 | H | Serial Input Clock- | Clock Input for Hexadecimal Code Serial Input Register on Pin A Furthermore, it allows for the selection of the serial or parallel operating mode of this code. <br> When ISA input goes low, the validated code is : <br> - the parallel input code if input H is high. <br> - the serial input code if input H is low. |
| 2 | ISA | Logic Input | This pin allows for the inhibition of the analog output MF OUT : <br> - when ISA is high, output MF OUT is idle and connected to $\mathrm{V}^{-}$. <br> - when ISA is low, the hexadecimal code is validated and MF OUT output is activated. |
| 8 | SA | Logic Output | This pin indicates the state of the analog output: <br> - if ISA is low, SA is a low impedance output at $\mathrm{V}^{-}$. <br> - if ISA is high, SA is a high impedance output. |
| 14 | MF OUT | Analog Output | This pin is the DTMF signal output. |
| 5 | OSC IN | Oscillator Input | This pin corresponds to the input of the inverter of the oscillator. The nominal frequency of the oscillator is 3.579 MHz . |
| 7 | OSC OUT | Oscillator Output | This pin corresponds to the output of an inverter with sufficient loop gain to start and maintain the crystal oscillating. |

ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $\mathrm{V}^{+}$ | Supply Voltage | -0.3 to +5.5 | V |
| $\mathrm{~V}_{\text {in }}$ | Digital Input Range | -0.3 to $\mathrm{V}^{+}+0.3$ | V |
| $\mathrm{~T}_{\text {stg }}$ | Storage Temperature Range | -55 to +125 | ${ }^{\circ} \mathrm{C}$ |

ELECTRICAL OPERATING CHARACTERISTICS
All voltages referenced to $V$

| Symbol | Parameter | Min. | Typ. | Max. | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{V}^{+}$ | Positive Supply Voltage | 3 | - | 5.25 | V |
| $\mathrm{~T}_{\text {oper }}$ | Operating Temperature Range | -25 | - | 70 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{f}_{\mathrm{c}}$ | Crystal Frequency | - | 3.579545 | - | MHz |

## DC ELECTRICAL CHARACTERISTICS

$\mathrm{T}_{\mathrm{amb}}=-25^{\circ} \mathrm{C}$ to $70^{\circ} \mathrm{C}, \mathrm{V}^{+}=-3$ to $5.25 \mathrm{~V}, \mathrm{f}_{\mathrm{c}}=3.579 \mathrm{MHz}$ (all voltages are referenced to $\mathrm{V}^{-}$)

| Symbol | Parameter | Min. | Typ. | Max. | Unit |
| :---: | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{I}_{\mathrm{DD}}$ | Operating Current in Transmission Mode ( $\mathrm{V}^{+}=4 \mathrm{~V}$, output <br> not loaded) | - | 0.6 | 1 | mA |
| ISB | Standby Current (ISA, H, A, B, C, D open circuit or <br> connected to $\mathrm{V}^{+}$) | - | - | 10 | $\mu \mathrm{~A}$ |
| $\mathrm{~V}_{\mathrm{IL}}$ | Input Low Voltage (ISA, H, A, B, C, D) | 0 | - | $0.3 \mathrm{~V}^{+}$ | V |
| $\mathrm{V}_{\text {IH }}$ | Input High Voltage (ISA, H, A, B, C, D) | $0.7 \mathrm{~V}^{+}$ | - | $\mathrm{V}^{+}$ | V |
| $\mathrm{R}_{\mathrm{T}}$ | Pull up Resistor on Logic Inputs ISA, H, A, B, C, D | 100 | - | - | $\mathrm{k} \Omega$ |
| $\mathrm{I}_{\text {OLSA }}$ | SA Output Current (VoLSA $=0.5 \mathrm{~V}$ ) | 500 | - | - | $\mu \mathrm{A}$ |

## FUNCTIONAL DESCRIPTION

With ISA input at logic level "1", the device is in low power mode. The oscillator is inhibited and analog output MF OUT is at ground level. DTMF input data is detected on trailing edge of ISA. This transition enables both the oscillator and the analog output then the data is stored and corresponding DTMF pair is generated during the low state interval of the ISA signal. Any modification to H, A, B, C and D signals during this period will not have any further effect on DTMF pair generated.

The device accepts input data in two different formats :

- Parallel format : this requires 4 connections (A, $B, C, D)$ between the microprocessor and the circuit.
- Serial format : in this case data is supplied to the circuit by the microprocessor via 2 connections A and H (see typical application diagram).

Pre-emphasis is applied to high group tone and both tones of DTMF pair are supplied through analog output pin.

## DATA ACQUISITION LOGIC

This section includes: A 4-bit shift register, an 8-line to 4-line multiplexer and a 4-bit storage register.

- The 4 -bit shift register has its input connected to pin A and is enabled by the signal applied to pin H. Its outputs are AS, BS, CS and DS signals.
- The multiplexer is enabled by signal H and operates according to the following law : $\mathrm{Al}=\mathrm{H} . \mathrm{AP}$ + $\overline{\text { H.AS. }}$
- The 4 -bit storage register operates on trailing edge of ISA signal. $\mathrm{Al}, \mathrm{BI}, \mathrm{Cl}, \mathrm{DI}$ and $\mathrm{AL}, \mathrm{BL}, \mathrm{CL}$, $D L$ are its inputs and outputs respectively.
During the low state period of ISA input, AL, BL, CL and DL signals determine the DTMF pair to be generated.

Figure 2 : Example of Parallel Operating Mode.

Note : If the circuit operates permanently in parallel mode, then the H input may be left floating (internally pulled-up to $\mathrm{V}^{+}$) or tied to logic 1. With ISA at logic $0, H, A, B, C$, and D inputs cannot modify the generated DTMF pair.

Figure 3 : Example of Serial-Operating Mode.

Notes : 1. With ISA at logic $0, H, A, B, C$ and $D$ signals cannot modify the generated DTMF pair. As a result, in serial operating mode, it is possible to enter AS, BS, CS and DS data while another DTMF pair is being generated.
2. First data to be entered is DS.

## DUAL TONE MULTIFREQUENCY GENERATOR

- 2.4 TO 4 V SUPPLY RANGE
- VERY LOW POWER CONSUMPTION
- ON-CHIP CRYSTAL CONTROLLED OSCILLATOR ( $\mathrm{f}_{0}=4.433619 \mathrm{MHz}$ ) WITH INTEGRATED FEEDBACK RESISTOR AND LOAD CAPACITORS
- LOW HARMONIC DISTORTION ( $\leq 2 \%$ )
- FIXED PRE-EMPHASIS ON HIGH-GROUP TONES
- FAST START-UP TIME
- LOW POWER CONSUMPTION IN STANDBY MODE
- MUTE OUTPUT
- ONE CONTACT PER KEY

## DESCRIPTION

The M761 provides all the tone frequency pairs required for a DTMF Dialling System. Tones are obtained from an inexpensive TV crystall ( $\mathrm{f}_{0}=$ 4.433619 MHz ) followed by two independent programmable dividers. The dividing ratio is controlled by the selected key. Keyboard format is 4 rows $\times 4$ columns and a key is valid when a column and a row are connected together.
Internal logic prevents the transmission of illegal tones when more than one key is pressed. If no key is selected the oscillator turns off and the linear parts are strobed to decrease the total power consumption.

As any buttom is pressed row and column inputs are scanned internally, to identify the activated ones. Electrically, row and column inputs are activated on high level voltage.
Single tone output cannot be emitted by a "1" an a row or column only. For single tone emission see "Single tone procedure".
A debounce output is available to indicate that a key has been selected. D/A conversion is accomplished by a capacitive network allowing very low power consumption, very low distortion and an exceptional stability of tone level against temperature variations.
The tones are mixed in a resistive network ; a unity gain amplifier is provided to realize a two pole active filter with only four external passive components.

The M761 can be interfaced with the speech circuit family LS156, LS356, LS656 with MF interface avoiding the need of the common spring set.
The M761 utilizes low voltage CMOS technology and is available in 18 pin dual in-line plastic package.

Notes: 1. This device has been designed to be connected to the DTMF interface of the speech circuit family LS156, LS356, LS656 from which it takes a $V_{D D}=2.4 \mathrm{~V}$ min. Therefore many parameters are tested at this value.
2. The value of DC output component at two different conditions of supply voltage, with two tones activated, can be related as follows:

$$
V_{D C}=V_{D C} \frac{V_{D D}}{V_{D D}}
$$

3. The value of $A C$ output components ( $V_{L F}, V_{H F}$ ) at two different conditions of supply voltages can be related as follows :
$V_{L F}=V_{L F} \frac{V_{D D}}{V_{D D}}$
$V_{H F}=V_{H F} \frac{V_{D D}}{V_{D D}}$
The values are measured with two tone at the output.

$$

The values are measured with two tone at the output.

## FUNCTIONAL DESCRIPTION

OSCILLATOR (OSC. IN - OSC. OUT)
The oscillator circuit has been designed to work with a 4.433619 MHz crystal ensuring both fast startup time and low current consumption.
When $V_{D D}$ is applied and a key is activated two inverters are paralleled (see fig. below) to decrease the total ron resistance.
After oscillations have started one of the two buffers
is switched off and the current consumption is reduced to $2 / 3$ of the initial value.
Feedback resistance and load capacitances are integrated on the chip ensuring good temperature performance.
When the device is supplied but no key is activated, the oscillator is in the stand-by mode to minimize power consumption.

KEYBOARD INPUTS
(C1, C2, C3, C4-R1, R2, R3, R4)
Each keyboard input has an internal protection circuit ; when a button is pressed, the oscillator starts and dynamic scanning of keyboard is realised.
This allows to the detection of which button has been pressed.
When two or more column or row inputs are activated no tone is generated.

## DIGITAL FREQUENCY OUTPUT

This output is intended for testing only ; when a single tone is activated, at this output is available a digital signal whose frequency is 16 times the selected output tone frequency. This output is an open collector N -channel transistor.

## MIXER OUTPUT

The two reconstructed sine waves are buffered then mixed in a resistive array network that also restores the DC output level.

## FILTER (Filter Input, Filter Output)

A unity gain amplifier is available to realize a two pole active filter (see fig. below). The output of this amplifier is held low until tones are valid, it than rises to about 0.85 V at $\mathrm{V}_{\mathrm{DD}}=2.5 \mathrm{~V}$.
Tones are superimposed on this DC.
The output DC component is very precise and stable to allow DC coupling with the LS156 speech circuit with MF interface.
The output dynamic impedance of the filter is about $2.5 \mathrm{~K} \Omega$.

The following equivalent circuit should be applied during filter design :

It is evident that R1 and R2 should be kept high to avoid undue influence of Mixer and Filter output impedances.

The following values are suggested :
R1 $=56 \mathrm{~K} \Omega \pm 2 \%$
R2 $=33 \mathrm{~K} \Omega \pm 2 \%$
$\mathrm{C} 1=2.2 \mathrm{nF} \pm 10 \%$
$\mathrm{C} 2=0.56 \mathrm{nF} \pm 10 \%$

## MUTE OUTPUT

Mute output becomes active when a key is activated eliminating keyboard bounces and remains active for all the duration of tone transmission.
If the key is released before the oscillator produces the correct control signals, mute output is disabled.

## SINGLE TONE PROCEDURE

This is accomplished through the following steps :

1) Activate simultaneously R1, R4, C1, C4 inputs, appling logic $1^{\prime} \mathrm{S}$. This implies the use of logic level sources. The single contact keyboard does not allow this procedure.
2) The device enters the "test mode" Now any single row or column frequency (or both) can be activated at output applying logic "1" to correspondant input (inputs).
3) To get out from "test mode" reply R1, R4, C1, C4, activation or power off/power on.

## DESCRIPTION

The M3561 is a single chip silicon-gate C-MOS integrated circuit. It is intended to convert push button keyboard entries into streams of correctly-timed line current interruptions. The input data is derived from a telephone keyboard with a $3 \times 4$ push button matrix. Numbers with up to 32 digits can be retained in a RAM for redial. Access pause can be stored via the keyboard.

## GENERAL DESCRIPTION

## 1. Pin Description

Y4; Y3; Y2; Y1 (pins 1 through 4)
Row keyboard input pins

## $\overline{\mathrm{CE}}$ (pin 5)

Chip Enable input pin. It is used to initialize the system, to select between the operational mode and the static standby mode, to handle line power breaks.

RE ; CD ; RD (pins 6 through 8)
Oscillator pins. These pins are used to connect external resistors RD, RE and capacitor CD to form a R-C oscillator that generates the time base for the Key Pulser. The output dialing rate and IDP are derived from this time base.

## $\overline{\mathrm{DP}}$ (pin 9)

Dial Pulse output pin. This signal is provided to drive the external line switching transistor or relay. The output will be "low" during "space" and "high" otherwise.

VSS (pin 10)
Negative supply input pin.

## $\overline{\mathrm{M} 1}$ (pin 11)

Mute output pin. This signal can be used to mute the receiver during the dialling sequence.

## M/S (pin 12)

Mark/Space selection input pin. This pin controls the mark to space ratio of the line pulses :
$M / S=\operatorname{VSS}(33.3 / 66.6) ; M / S=\operatorname{VDD}(40 / 60)$.
M/S has an internal pull-up resistor.

## VDD (pin 13)

Positive Supply input pin.
IDS (pin 14)
This pin must be connected to Vss.

## APE (pin 15)

This pin must be connected to Vss.
X1; X2 ; X3 (pins 16 through 18)
Column keyboard input pins.

Table1 : Table for selecting oscillator component values for desired dialing rates and inter-digit pauses.

| Osci. | - RD | RE | CD | Dial Rate (pps) | IDP (ms) |
| :---: | :---: | :---: | :---: | :---: | :---: |

Table 2 : Input Pin Selection.

| Function | Pin | Input Level | Selection |
| :--- | :---: | :---: | :---: |
| Mark/space Ratio | $\mathrm{M} / \mathrm{S}$ | $\mathrm{V}_{\text {SS }}$ | $1: 2$ |
|  |  | $\mathrm{~V}_{\text {DD }}$ | $1: 1.5$ |
| Chip Enable | $\overline{\mathrm{CE}}$ | $\mathrm{V}_{S S}$ | Off-hook |
|  |  | $\mathrm{V}_{D D}$ | On-hook |

## 2. Clock Oscillator

This device contains an oscillator circuit that requires three external components : two resistors (RD and RE) and one capacitor (CD). All internal timing is derived from this master time base. To eliminate clock interference in the talk state, the oscillator is only enabled during key closures and during the dialing state. It is disabled at all other times, including the "on hook" condition. For a dialing rate of 10 pps , the oscillator should be adjusted to 2400 Hz . Typical values of external components for this are RD $=715 \mathrm{Kohm}$ and $R E=750 \mathrm{Kohm}$ and $C D=270 \mathrm{pF}$.
It is recommended that the tolerance of resistors be $1 \%$, and that of the capacitor be $5 \%$, to insure a $\pm 10 \%$ tolerance of the dialing rate in the system.

## 3. Chip Enable ( $\overline{\mathrm{CE}}$ )

The CE input is used to initialize the chip system.
$\overline{\mathrm{CE}}=$ High provides the static standby condition. In this mode, the clock oscillator is off, and internal registers are clamped in reset, with the exception of WRITE ADDRESSCOUNTER (WAC). The keyboard input is inhibited, but data previously entered is saved in the RAM.
When $\overline{\mathrm{CE}}=$ Low, the clock oscillator is again off but the internal registers are enabled and data can be entered from the keyboard. After the first keyboard entry the clock oscillator starts.
If the $\overline{\mathrm{CE}}$ input is taken to a High level for more than
the time trd (see figures 3 and 4 and timing data), an internal reset pulse will be generated at the end of the trd period. The system is then is the static standby mode.
Short $\overline{\mathrm{CE}}$ pulses of < trd will not affect the operation of the circuit. No reset pulses are then produced.

## 4. Debouncing Keyboard Entries

The column keyboard inputs to the integrated circuit $(\mathrm{Xn})$ and the row keyboard inputs ( Yn ) are for direct connection to a $3 \times 4$ single contact keyboard matrix (with or without common contact), as shown in fig. 1, or to a double contact keyboard with a common connected to VDD (see figure 2). An entry is decoded into a 4-bit binary keycode by the keyboard decoder when one column input is connected to one row input, or when one column input and one row input are set High. Any other input combinations will be judged to not be valid and will not be accepted.
Valid inputs are debounced on to the leading and trailing edges, as shown in figure 3 : Keyboard entries are only decoded into 4-bit binary keycodes and written into the RAM if the keyboard contact remains closed for four or five clock pulse periods (entry period te). The next keyboard entry will not be accepted until the previously closed contact has been open for three or four clock pulse periods. The one clock pulse period of uncertainty in the debouncing process arises because keyboard entries are not detected until the trailing edge of the first clock pulse after the entry.

Figure 1 : Single Contact Keyboard.

\# Key : Redial or Set/Reset Access Pause.

## Figure 3.

Timing diagram showing clock start-up, keyboard entry debouncing and the effect of interrupting the supply. to $\overline{\mathrm{CE}}$ during the transmission of dialing pulses.

(1) Static Standby Mode.
(2) Dialing Mode.

## 5. Data Storage and Data Retrieval

After each keyboard entry has been debounced and decoded, the keycode is written into the RAM and the WAC is incremented by one to select the next RAM location where the next keycode will be stored. As each keycode is recalled from the RAM for line pulsing, the READ ADDRESS COUNTER (RAC) is incremented by one to select the RAM location of the next keycode to be recalled. Consequently, the difference between the contents of the WAC and of the RAC represents the number of keycodes that have been written into the RAM, but not yet converted into line pulses.
If more than 32 keycodes are written into the RAM, memory overflow results and the excess keycodes replace the data in the lower-numbered RAM locations. In this event, since an erroneous number is stored, automatic redialing is inhibited until the WAC has been reset by the first digit entry of the next telephone call.
If the first push button to be pressed is not redial (\#), the WAC is reset during entry time te, the corresponding keycode is written into the first RAM location and the WAC is then incremented by one to select the next RAM location. Consequently, if the first push button pressed is not redial, the data stored previously in the RAM cannot be redialed anymore.
If the first push button is redial (\#), the WAC is not reset and the keycodes stored in the RAM are sequentially recalled and converted into correctly timed dialing pulses at output $\overline{\text { DP }}$. If the redial push button (\#) is operated again during the redialling sequence, it will be decoded as an Access Pause Reset. This function will be described later during the description of the access pause system of the M3561. During and after redial, new keyboard entries will be accepted, and converted into correctly timed dialing pulses. These new keyboard are not stored in RAM.

## 6. Dialing Sequence

The dialing sequence can be initiated under the following conditions:

- The supply to the integrated circuit is derived from the telephone lines via the cradle contacts (power supply before keyboard entry) ; see fig. 4.
Then, approximately 1 ms (ten) after CE goes Low, the clock pulse generator is enable, and the circuit is in the conversation mode, while the subscriver waits for the dialing tone. When the first digit of the required number is entered at the keyboard, the clock oscillator starts and data entry period te begins.
The further dialing sequence will be described with the aid of fig. 4. When the keyboard entry has been decoded and written into the RAM, M1 goes LOW to mute the telephone with a delay of about one Inter Digit Pause time ( 1.1 *tid), the RAC addresses the RAM and the first keycode is loaded into the register of the output counter, which generates the appropriate number of correctly timed dialing pulses at output DP.
When the digit has been pulsed out, $\overline{\mathrm{M} 1}$ goes HIGH, at least for one IDP, the RAC is incremented by one, and the procedure repeats until the WAC and RAC contents are equal (all digits pulsed out).
When $\overline{\mathrm{M} 1}$ is High, the circuit assumes the conversation mode. The circuit reverts to the static standby mode if CE goes High for more than the reset delay time (trd) at any time during the conversation or dialing mode (e.g., because the handset is replaced). CE remains High although VDD is maintained by a backup supply (e.g., because an external diode isolates CE from the back-up supply connected to VDD). The RAM retains its contents for subsequent automatic redialing as long as the back-up supply maintains VDD above VDR $=1 \mathrm{~V}$.

Figure 4.
Timing diagram of dialing sequence with $V_{D D}$ and $\overline{C E}$ Low before keyboard entry (e.g., supply via the cradle contacts).

(1) Oscillator off. All registers except WAC reset. Keyboard input inhibited. Number stored in RAM until VDD $>=1 \mathrm{~V}$.

## 7. Storage and Regeneration of Access Pauses

A dial sequence may require an extended Inter Digit Pause if it is necessary to wait for the dial tone. During the keyboard entry, whenever an access pause is needed, a pause code can be stored in the RAM, via the keyboard (\# key) for a later redial sequence. When an access pause is regenerated during redialing, it can be terminated via keyboard (\# key).
A pause code takes one position in the RAM like a digit. The number of digits plus the number of access pauses cna therefor bu up to 32 .
7.1. MANUAL PAUSE. Access pause codes can be stored in the RAM at appropriate positions by pressing the access pause key (\# key). A manual pause code can be stored after any digit. The maximum number of manual pause codes is not limited. Consecutive manual pause codes will generate a single pause during redial.
During the redial sequence the manually stored codes will automatically generate pauses. The duration of the manual pause is unlimited. Whenever a manual pause code is read from the RAM, the normal Inter Digit Pause is extended until it is terminated manually by presssing key \#.

## 8. Summary of Special Keyboard Functions

Kéy \# : Inserts a manual pause code, if activated after a number key, or terminates a manual pause, if activated during the pause.

Key \# : Starts the redial sequence, if activated as first key after off-hook.

## 9. Statc Standby Operation

$\overline{\mathrm{CE}}$ : HIGH turns off the oscillator and resets all internal registers, with the exception of the WRITE ADDRESS COUNTER and the RAM. All input pullup and pull-down devices are switched off. The current consumption is reduced in this condition such that the supply voltage required to hold the data stored in the RAM can be provided by a capacitor.

## 10. Selection of Extra Digits During or After Redial

## Case 1

1th selection
Keyboard

Emission

RAM

Redial

Emission

RAM

| 1 | 2 | 3 | 4 |
| :--- | :--- | :--- | :--- |

Comment : The key entries $\quad 8$ and $\quad 9$ after "Redial" are dialed buty not memorized.

## Case 2

1st selection

Emission

RAM

Redial

RAM | 1 | 2 | 3 |
| :--- | :--- | :--- |

Comment : The first key $\#$ is used as "Redial", the other keys $\quad \#$ are ignored because no manual pause was memorized during the first selection.

## Case 3

1st selection

RAM

Redial

RAM

Comment : during the first selection if many keys rized in the RAM. In the second selection the first

are pressed consecutively only one is memokey is used as Redial, the second is ignored since the emission is still going and the third ends the manual pause inserted in the first selection.

## 11. Multiple Key Pressing

If two keys are pressed at the same time, the following operation will take place.
Case 1

"b" key

M89M3551-04

These key inputs will be completely ignored.
Case 2

The "a" key input wil be ignored.
The "b" key input will be read from this point $\binom{1}{\mathrm{l}}$

## Case 3

The "a" key input will be read from this point $\binom{1}{1} \quad$ The " b " key input will be ignored.

## Case 4

The "b" key input will be read from this point ( $\left.\begin{array}{l}1 \\ 1\end{array}\right)$.
Consequently the "b" key is read once and the "a" key is ignored.

## Case 5

M89M3561-08
The "a" key input wil be read from 1st point $\binom{\mid}{ 1} . \quad$ The "b" key input will be read from 2nd point $\binom{l}{1}$. Consequently the "a" key and the "b" key are read once each.-

## SINGLE NUMBER PULSE TONE SWITCHABLE DIALER WITH SAVE FACILITY

- SELECTABLE LOOP DISCONNECT OR DTMF DIALLING MODES
- ALLOWS USER TO SWITCH FROM LD TO DTMF DIALLING DURING A CALL
- LNR FACILITY ALLOWS UP TO 32 DIGITS TO BE RETAINED FOR REDIALLING
- SELECTABLE MAKE/BREAK RATIOS $2: 1$ AND 3 : 2
- SELECTABLE INTERDIGIT PAUSE 500 ms OR 800 ms
- USES INEXPENSIVE 560KHz RESONATOR
- TIMED BREAK RECALL (timed flash)
- OPERATES WITH INEXPENSIVE SINGLE CONTACT KEYPAD
- CAPABLE OF BATTERY-LESS OPERATION. LOW POWER CMOS PROCESS ALLOWS DIRECT OPERATION FROM TELEPHONE LINES

## DESCRIPTION

The M3540 is a keypad switchable LD/DTMF dialer devices designed for use in low cost, dual dialing mode telephone instruments. It is suitable for sending telephone numbers without limit and an on-chip memory allows numbers of up 32 digits to be retained for redialling later. The low power CMOS design allows the number in the memory to be maintained indefinitely (until overwritten) by a minimal current leaked from the telephone line. A particular feature of this device is the facility for the user to switch dialling mode from LD to DTMF via the keypad during the course of a call. This is intended for uses such as home banking, access to long distance trunk service, credit card verifications and other applications which require data to be sent at low speed once a connection has been established.

## PIN CONNECTION

## ABSOLUTE MAXIMUM RATINGS*

| Symbol | Parameter | Value |  |  | Unit |

PIN FUNCTIONS

| Pin Name | Function |
| :---: | :---: |
| ROW 1 ROW 2 ROW 3 ROW 4 COL 1 COL 2 COL 3 COL 4 | Connections for 16 Buttons, Single Contact Keyboard |
| $V_{\text {DD }}$ | Positive Supply |
| $V_{S S}$ | Negative Supply |
| SELECT | LD/MF Selection, IDP and B/M Ratio Programming |
| $\begin{aligned} & \text { OSCIN } \\ & \text { OSCOUT } \end{aligned}$ | Oscillator Connection |
| HSW | Hookswitch. A logic '1' voltage at this pin is used to indicate 'off-hook'. |
| MASK | Output to disable speech circuit during pulse dialling and recall (see note 1). |
| IMP | 'Loop Disconnect' Dialling Output |
| MF OUT | Unfiltered, Dual Tone Output |
| FILTOUT FILTIN | Unity Gain Amplifier Input and Output for 2-pole Filter |
| MUTE | Output Active During Keying and Tone Transmission (see note 2) |

Notes: 1. The $\overline{\text { MASK }}$ output may be used to disconnect the whole speech circuit in order to maintain the break condition whilst on-hook, during a TBR (timed flash) operation or for LD dialling.
2. The MUTE output is provided to disable the microphone while maintaining the loop condition during DTMF transmission.

## KEYPAD OPERATION

The device will accept keypad inputs only in the 'offhook' condition when the key is pressed for more than 14 ms . Any key pressed during the 'on-hook' condition will be ignored and the oscillator inhibited. This ensures that the current drain 'on-hook' is low and used only for memory retention.

## KEYPAD FORMAT

C1 C2 C3 C4

TBR $\quad=$ Timed Break Recall (Timed Flash)
SAVE = Save digits dialled since going off-hook
REDIAL = Redial digits in 'save' store
TONE = Change dialling mode from LD to DTMF

* and \# are available in DTMF mode only

## LD/DTMF MODE SELECTION

The initial dialling mode after the telephone goes off-hook is determined as follows :
DTMF - Connect SELECT pin to VDD

| Option |  | Connect SELECT <br> pin to $:$ |
| :---: | :---: | :---: |
| IDP | B/M Ratio |  |
| 800 ms | $2: 1$ | VSS |
| 500 ms | $2: 1$ | COL 1 |
| 500 ms | $3: 2$ | COL 2 |
| 800 ms | $3: 2$ | COL 3 |

LD dialing is at 10 p.p.s. for all options

## KEYPAD LD/DTMF MODE CHANGE

Pressing the TONE key at any time after going offhook will cause subsequently entered digits to be dialled in DTMF. If the TBR (Timed Flash) key is Pressed, or an Earth Loop Recall operation is si-
gnalled to the chip, further dialling is set to the initial mode again.
In order to signal an ELR operation to the chip, the following configuration should be adopted :

Figure 1.

## 'SAVE' STORE OPERATION

The 'save' store is 31 digits long. If the user attempts to save a number of more than 31 digits the store is inhibited. The contents of the 'save' store are maintained until overwritten.
To load the 'save' store :
At any time whilst off-hook the SAVE key may be pressed. This action causes digits dialled since going off-hook to be retained, and the previous contents of the store are overwritten. Further digits may be dialled after pressing the SAVE key but these will not be retained.
To redial the number in the 'save' store :
Whilst in the speech mode, press REDIAL once.
However, if an LD to DTMF mode change was effected when the number was originally dialled, a marker* in the 'save' store will cause the redialling
to pause at this point and the speech circuit will be reactivated. If the REDIAL key is then pressed again, the remaining digits in the store will be redialled in DTMF.
If the redial feature is invoked after going off-hook, the digits in the 'save' store will be redialled as described above. If the redial feature is not invoked after going off-hook, it is possible to first key in digits and then press REDIAL. If the digits keyed in correspond with the first digits in the 'save' store, the remaining digits will be automatically redialled (this feature is provided to allow manual keying of an access code followed by a pause before dialling out the rest of the number). If, however, a digit is keyed which differs from the corresponding digit in the store number, then redialling is inhibited.

* This marker requires one location of the 31 digit store

## LAST NUMBER REDIAL

The function of the Last Number Redial store is to automatically retain the last number dialled so that it can be redialled later simply by pressing the LNR key. Either LD or MF numbers will be retained in the store. When numbers containing an LD part followed by an MF part are dialled, only the LD part will be retained in order that security codes, etc., dialled in MF are not automatically stored.
To redial a number, go off-hook and press LNR. once. Alternatively, digits may be keyed manually before LNR is pressed. If.the digits keyed correspond with the first digits in the LNR store, the remaining digits will be automatically redialled when LNR is pressed (this feature allows manual keying of an access code followed by a pause before dialling out the rest of the number). If, however, a digit is keyed which differs from the corresponding digit in the stored number, then redialling is inhibited.

## HOOKSWITCH OPERATION

The hookswitch input is used to inform the M3540 of whether the telephone is on- or off-hook. When the telephone is on-hook the M3540 will adopt a static low power mode in which dialling functions are inhibited and only a minimal current is consumed to maintain the store contents.

The M3540 recognises the on-hook condition when the hookswitch input (HSW) goes from logic '1' (the off-hook condition) to logic '0' for greater than 300 ms . Short line voltage interruptions of less than 200 ms , such as those created by the exchange during connection, will not be recognised by the M3540 as an on-hook indication.
The MASK output will go to logic '0' instantly whenever, and for as long as, the hookswitch input is at logic ' 0 ' in order to disconnect the speech circuit. This conserves current so that the store contents are not lost.

## POWER-ON RESET

A Power-on Reset is internally generated when power is applied to the chip and causes the number store to be cleared.

## LOOP DISCONNECT MODE

In this mode the $\overline{\text { MASK }}$ output is used to disable the speech circuit during dialling. The MASK output is at logic '0' during impulsing and interdigit pauses.
The IMP output signals a break to line when at logic '0' (Vss). Make periods and I.D.P. times are signalled by logic ' 1 ' on the output. During the non-dialling period the impulsing output is at logic ' 0 '. Timing of the output is shown below.

Figure 2 : Timing Diagram.

Figure 3 : Timing Data.

## DTMF MODE

The MUTE output goes to logic ' 1 ' when a key is activated and remains active for the duration of the
tone transmission.
The tone rate will be 100 ms on, 100 ms off minimum.

TONE FREQUENCIES

| Keypad | R1 | R2 | R3 | R4 | C1 | C2 | C3 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Nominal Frequency (Hz) | 697 | 770 | 852 | 941 | 1209 | 1336 | 1477 |
| Deviation from Nominal (\%) | -0.07 | -0.10 | -0.19 | -0.15 | -0.17 | -0.20 | -0.22 |

There will be an additional error due to the deviation of the oscillator frequency from 560 KHz .
Figure 4 : Timing Diagram.

SGS-THOMSON

## TONE OUTPUT

Facility has been made for tone filtering as shown below. This also allows the user to adjust tone amplitudes as required. The tone amplitude is propor-
tional to the chip supply voltage, $\mathrm{V}_{\mathrm{DD}}$, and can be adjusted by changing the ratio of $R_{3}$ and $R_{4}$

Figure 5.

The filter components shown have been chosen to give a second order Butterworth response with a cut-off frequency of about 3.5 KHz . The pass-band insertion loss is nominally 0.5 dB .

## DTMF APPLICATION CIRCUITS

The DTMF circuit in figure 2 uses a constant current supply and a 2.5 V reference diode to produce the stabilised supply voltage which determines the MF tone level of the M3540. If the speech circuit provides a stabilised voltage, then figure 3 shows how
it may be used to power the M3540 Diode D1 prevents the speech circuit from taking current whilst the telephone is on-hook, and D2 compensates for the voltage dropped across D1 when off-hook.

Figure 6.

Figure 7.

## SWITCHABLE LD/MF APPLICATION CIRCUITS

The circuit in figure 4 uses a constant current supply to take current from the telephone line which is used to power the M3540. The 2.5 V reference diode produces a stabilised supply voltage which determines the MF tone level of the M3540.
In figure 5, a stabilising voltage from the speech cct is used to supply the M3540 during MF dialling to give accurate tone levels.

The M3540 is powered via the 150 K resistor during TBR operations and LD dialling breaks, and via Q1 during dialling makes. This configuration minimises the component count at the expense of allowing a leakage current of about $450 \mu \mathrm{~A}$ during dialling breaks. The $47 \mu \mathrm{~F}$ reservoir capacitor maintains and smooths the supply to the chip.

Figure 8.

Figure 9.

## SINGLE NUMBER PULSE TONE SWITCHABLE DIALER

- SELECTABLE LOOP DISCONNECT OR DTMF DIALLING MODES
- ALLOWS USER TO SWITCH FROM LD TO DTMF DIALLING DURING A CALL
- LNR FACILITY ALLOWS UP TO 32 DIGITS TO BE RETAINED FOR REDIALLING
- SELECTABLE MAKE/BREAK RATIOS 2:1 AND 3:2
- SELECTABLE INTERDIGIT PAUSE 500ms OR 800ms
- USES INEXPENSIVE 560KHz RESONATOR
- TIMED BREAK RECALL (timed flash)
- OPERATES WITH INEXPENSIVE SINGLE CONTACT KEYPAD
- CAPABLE OF BATTERY-LESS OPERATION. LOW POWER CMOS PROCESS ALLOWS DIRECT OPERATION FROM TELEPHONE LINES

## DESCRIPTION

The M3541 is a keypad switchable LD/DTMF dialer devices designed for use in low cost, dual dialing mode telephone instruments. It is suitable for sending telephone numbers without limit and an on-chip memory allows numbers of up 32 digits to be retained for redialling later. The low power CMOS design allows the number in the memory to be maintained indefinitely (until ovenwritten) by a minimal current leaked from the telephone line. A particular feature of this device is the facility for the user to switch dialling mode from LD to DTMF via the keypad during the course of a call. This is intended for uses such as home banking, access to long distance trunk service, credit card verificatios and other applications which require data to be sent at low speed once a connection has been established.

ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter | Value |  |  | Unit |
| :--- | :--- | :---: | :---: | :---: | :---: |

PIN FUNCTIONS

| Pin Name |  |
| :---: | :--- |
| ROW 1 |  |
| ROW 2 |  |
| ROW 3 |  |
| ROW 4 | Function |
| COL 1 | Connections for 16 Buttons, Single Contact Keyboard |
| COL 2 |  |
| COL 4 |  |
| VDD | Positive Supply |
| VSS | Negative Supply |
| SELECT | LD/MF Selection, IDP and B/M Ratio Programming |
| OSCIN | Oscillator Connection |
| OSCOUT | Hookswitch. A logic '1' voltage at this pin is used to indidcate 'off-hook'. |
| HSW | Output to disable speech circuit during pulse dialling and recall (see note 1). |
| MASK | 'Loop Disconnect' Dialling Output |
| IMP | Unfiltered, Dual Tone Output |
| MF OUT | Unity Gain Amplifier Input and Output for 2-pole Filter |
| FILTOUT |  |
| MUTTIN | Output Active During Keying and Tone Transmission (see note 2) |

Notes : 1. The MASK output may be used to disconnect the whole speech circuit in order to maintain the break condition whilst on-hook, during a TBR (Timed Flash) operation or for LD dialling.
2. The MUTE output is provided to disable the microphone while maintaining the loop condition during DTMF transmission.

## KEYPAD OPERATION

The device will accept keypad inputs only in the 'offhook' condition when the key is pressed for more than 14 ms . Any key pressed during the 'on-hook' condition will be ignored and the oscillator inhibited. This ensures that the current drain 'on-hook' is low and used only for memory retention.

## KEYPAD FORMAT

LNR = Redial digits in "LNR"store
TBR = Timed Break Recall (timed flash)

## LD/DTMF MODE SELECTION

The initial dialling mode after the telephone goes off-hook is determined as follows :

## DTMF - Connect SELECT pin to VDD

LD -

| Option |  | Connect SELECT <br> pin to : |
| :---: | :---: | :---: |
| IDP | B/M Ratio |  |
| 800 ms | $2: 1$ | V SS $^{2}$ |
| 500 ms | $2: 1$ | COL 1 |
| 500 ms | $3: 2$ | COL 2 |
| 800 ms | $3: 2$ | COL 3 |

## KEYPAD LD/DTMF MODE CHANGE

If the initial dialling mode is LD, pressing either the * or \# key will cause all subsequently entered digits to be dialled in DTMF. The first press of either * or \# will not cause a digit to be dialled, but once in MF mode, pressing * or \# will cause the appropriate tone pair to be transmitted.

LD dialling is at 10 i.p.s. for all options

Figure 1.

If the TBR (Timed Flash) key is pressed, or an Earth Loop Recall operation is signalled to the chip, further dialling is set to the initial mode.
In order to signal an ELR operation to the chip, the following configuration should be adopted :

## LAST NUMBER REDIAL

The function of the Last Number Redial store is to automatically retain the last number dialled so that it can be redialled later simply by pressing the LNR key. Either LD or MF numbers will be retained in the store. When numbers containing an LD part followed by an MF part are dialled, only the LD part will be retained in order that security codes, etc., dialled in MF are not automatically stored.
To redial a number, go off-hook and press LNR
once. Alternatively, digits may be keyed manually before LNR is pressed. If the digits keyed correspond with the first digits in the LNR store, the remaining digits will be automatically redialled when LNR is pressed (this feature allows manual keying of an access code followed by a pause before dialling out the rest of the number). If, however, a digit is keyed which differs from the corresponding digit in the stored number, then redialling is inhibited.

## HOOKSWITCH OPERATION

The hookswitch input is used to inform the M3541 of whether the telephone is on- or off-hook. When the telephone is on-hook the M3541 will adopt a static low power mode in which dialling functions are inhibited and only a minimal current is consumed to maintain the store contents.
The M3541 recognizes the on-hook condition when the hookswitch input (HSW) goes from logic '1' (the off-hook condition) to logic '0' for greater than 300 ms . Short line voltage interruptions of less than 200 ms , such as those created by the exchange during connection, will not be recognized by the M3541 as an on-hook indication.
The MASK output will go to logic '0' instantly whenever, and for as long as, the hookswitch input is at logic ' 0 ' in order to disconnect the speech circuit.

This conserves current so that the store contents are not lost.

## POWER-ON RESET

A Power-on Reset is internally generated when power is applied to the chip and causes the number store to be cleared.

## LOOP DISCONNECT MODE

In this mode the $\overline{\text { MASK }}$ output is used to disable the speech circuit during dialling. The MASK output is logic ' 0 ' during impulsing and interdigit pauses.
The IMP output signals a break to line when at logic ' 0 ' (VSS). Make periods and I.D.P. times are signalled by logic ' 1 ' on the output. During the non-dialling period the impulsing output is at logic ' 0 '. Timing of the output is shown below.

Figure 2. : Timing Diagram

Flgure 3. : Timing Data

$\mathrm{t}_{1}=$ Pre-digit pause (= ts)
$\mathrm{t}_{2}=$ Break period ( 60 ms or 67 ms )
$\mathrm{t}_{3}=$ Make period ( 40 ms or 33 ms )
$\mathrm{t}_{4}=$ Post-digit make ( $=\mathrm{t}_{3}$ )
$\mathrm{t}_{5}=$ Inter-digit pause ( 500 or 800 ms )

## DTMF MODE

The MUTE output goes to logic ' 1 '. when a key is activated and remains active for the duration of the
tone transmission.
The tone rate will be 100 ms on, 100 ms off minimum.

## TONE FREQUENCIES

| Keypad | R1 | R2 | R3 | R4 | C1 | C2 | C3 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Nominal Frequency (Hz) | 697 | 770 | 852 | 941 | 1209 | 1336 | 1477 |
| Deviation from Nominal (\%) | -0.07 | -0.10 | -0.19 | -0.15 | -0.17 | -0.20 | -0.22 |

There will be an additional error due to the deviation of the oscillator frequency from 560 KHz .
Figure 4 : Timing Diagram.

## TONE OUTPUT

Facility has been made for tone filtering as shown below. This also allows the user to adjust tone amplitudes as required. The tone amplitude is propor-
tional to the chip supply voltage, $\mathrm{V}_{\mathrm{DD}}$, and can be adjusted by changing the ratio of R3 and R4.

Figure 5.

The filter components shown have been chosen to give a second order Butterworth response with a cut-off frequency of about 3.5 KHz . The pass-band insertion loss is nominally 0.5 dB .

## DTMF APPLICATION CIRCUITS

The DTMF circuit in figure 6 uses a constant current supply and a 2.5 V reference diode to produce the stabilised supply voltage which determines the MF tone level of the M3541. If the speech circuit provides a stabilised voltage, then figure 7 shows how
it may be used to power the M3541. Diode D1 prevents the speech circuit from taking current whilst the telephone is on-hook, and D2 compensates for the voltage dropped across D1 when off-hook.

Figure 6.

Figure 7.

## SWITCHABLE LD/MF APPLICATION CIRCUITS

The circuit in figure 8 uses a constant current supply to take current from the telephone line which is used to power the M3541. The 2.5 V reference diode produces a stabilised supply voltage which determines the MF tone level of the M3541.

In figure 9, a stabilising voltage from the speech is used to supply the M3541 during MF dialling to give accurate tone levels.

The M3541 is powered via the 150K resistor during TBR operations and LD dialling breaks, and via Q1 during dialling makes. This configuration minimises the component count at the expense of allowing a leakage current of about $450 \mu \mathrm{~A}$ during dialling breaks. The $47 \mu \mathrm{~F}$ reservoir capacitor maintains and smooths the supply to the chip.

Figure 8.

Figure 9.

## SINGLE NUMBER PULSE TONE SWITCHABLE DIALER

- STAND-ALONE DTMF AND PULSE SIGNALING
- RECALL OF LAST NUMBER DIALED (up to 28 digits long)
- FORM-A AND 2-of -7 KEYBOARD INTERFACE
- PACIFIER TONE
- POWERED FROM TELEPHONE LINE, LOW OPERATING VOLTAGE FOR LONG LOOP APPLICATIONS

## DESCRIPTION

The MK5370 is a Silicon Gate CMOS IC that provides necessary signals for either DTMF or loop disconnect (pulse) dialing. The MK5370 buffers up to 28 digits into memory that can be later redialed with a single key input. This memory capacity is sufficient for local, long distance, overseas, and even computerized long-haul networks. Users can store all 12 signaling keys and redial them using either the *or \# as the first key entry after going off-hook.

## KEYPAD CONFIGURATION

| 1 | 2 | 3 |
| :---: | :---: | :---: |
| 4 | 5 | 6 |
| 7 | 8 | 9 |
| $*$ <br> LND | 0 | $\#$ <br> LND |

M88MK5370-81

A *or \# key input automatically redials the last number dialed if it is the first key entered after a transition from on-hook to off-hook (HKS input switched from a high to low logic level). Auto-dialing is momentarily interrupted (during interdigital pause period or intersignal period) while manual keys are depressed, however these inputs are not stored into memory.

## ABSOLUTE MAXIMUM RATINGS *

| Parameter | Value | Unit |
| :--- | :---: | :---: |
| DC Supply Voltage | 6.5 | V |
| Operating Temperature | 0 to +60 | ${ }^{\circ} \mathrm{C}$ |

Notes : 1. 0 dBm equals 1 mW power into 600 ohms or 775 mVolts .
Important Note : The mk5370 is designed to drive a 10 Kohms load. The 600 ohms load is only for reference.
2. Single tone (low group). varies when used in subscriber set.
3. Supply voltage ? 2.5 to 6 Volts. $R_{E}=10$ kohms.
4. $\mathrm{R}_{\mathrm{E}}=10$ Kohms.
5. Supply voltage $=2.5$ Volts. These specifications are supply-dependent.
6. Time from beginning of tone output wavefform to $90 \%$ of final magnitude of either frequency Crystal parameters suggested for proper operation are $R_{s}=1000$ ohms $L_{m}=96 \mathrm{mH} \mathrm{C}_{\mathrm{m}}=0.2 \mathrm{pFC}_{\mathrm{m}}=5 \mathrm{pF} \mathrm{f}=3.579545 \mathrm{MHz}$ and $\mathrm{C}_{1}=18 \mathrm{pF}$.
7. Time from initial key input until beginning of signaling.

## FUNCTIONAL DESCRIPTION

V+
Pin 1. $\mathrm{V}_{+}$is the positive supply for the circuit and must meet the maximum and minimum voltage requirements. (see Electrical Specifications).

## MODE/TEST

Input. Pin 2. MODE/TEST determines the dialer's default operating mode. When the device is powered up or the hookswitch input is switched from onhook ( $\mathrm{V}_{+}$) to off-hook ( $\mathrm{V}-$ ) the default determines the signaling mode. A $V_{+}$connection selects to pulse mode operation.
Pin 2 also forces the device into test mode.
$\overline{\mathrm{C} 1}, \overline{\mathrm{C} 2}, \overline{\mathrm{C} 3}, \overline{\mathrm{R} 4}, \overline{\mathrm{R} 3}, \overline{\mathrm{R} 2}, \overline{\mathrm{R} 1}$
Keyboard Input. Pins 3, 4, 5, 13, 14, 15, 16. The MK5370 interfaces with either the standard 2-of-7 with negative common or the inexpensive singlecontract (Form A) keyboard.
A valid keypad entry is either a single Row connected to a single Column or V-simultaneously presented to both a single Row and Column. In its quiescent or standby state, during normal off-hook ope-
ration, either the Rows or the Columns are at a logic level $1\left(\mathrm{~V}_{+}\right)$. Pulling one input low enables the on-chip oscillator to begin scanning the keypad. Scanning consists of Rows and Columns alternately switching high through on-chip pull-ups.
After both a Row and Column key have been detected, the debounce counter is enabled and any noise (bouncing contacts, etc.) is ignored for a debounce period (Tdb) of 32 ms . At this time, the keyboard is sampled and if both Row and Column information are valid, the information is buffered into the LND location. If switched on-hook (pin 17 to pin 1), the keyboard inputs all pull high through on-chip pull-up resistors.

IC
Input. Pin 9 Internal connection. This pin should be left during for normal operation.

V-
Input. Pin 6 is the negative supply input to the device. This is the voltage reference for all specifications.

## OSC1; OSC2

Input/Output. Pins 7, 8. OSC1 and OSC2 are inputs to an on-chip inverter used as the timing reference for the circuit. It has sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation from this standard is directly reflected in the Tone output frequencies. The crystal oscillator provides the time reference for all circuit functions.

## DTMF OUTPUT

Output. Pin 10. An NPN transistor emitter with a collector tied to $\mathrm{V}+$ drives the DTMF OUTPUT pin. The transistor base is connected to an on-chip operational amplifier that mixes the Row and Column tones. Figure 4 shows the timing at this pin.
The DTMF OUTPUT is the summation of a single Row frequency and a single Column frequency. A typical single tone sine wave is shown in Figure 1. This waveform is synthesized using a resistor tree with sinusoidally weighted taps.
The MK5370 is designed to operate from a regulated supply and the row (low group) TONE LEVEL is related to this supply by either of the following equations:
$\mathrm{T}_{01}=20 \mathrm{LOG}[(0.0776 \mathrm{~V}+) / 0.775] \mathrm{dBm}$

$$
\mathrm{T}_{01}=0.0776(\mathrm{~V}+) \text { VRMS }
$$

The DC component of the DTMF output while active is described by the following equation :

$$
V_{D C 1}=0.66 \mathrm{~V}+-0.6 \text { Volts }
$$

Figure 1 : Single Tone.

## PACIFIER TONE OUTPUT

Output. Pin 11. A 500 Hz square waive is activated on pin 11 upon acceptance of a valid key input, after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. In pulse mode, all key entries activate the pacifier tone. In tone mode, only a redial entry activates the pacifier tone. The pacifier tone provides audible feedback, confirming that the key has been properly entered and accepted.

Figure 2 : Dual Tone.

Figure 3 : Spectral Reponse.

## MUTE1

Output. Pin 12. This pin is the Mute Output for both tone and pulse modes. Timing is dependent upon mode.

The output consists of an open drain N -channel device. During standby, the output is high impedance and generally has an external pull-up resistor to the positive supply.
In tone mode, MUTE1 removes the transmitter and the receiver from the network during DTMF signaling. During dialing, MUTE1 is active continuously until dialing is completed.
In pulse mode, $\overline{\text { MUTE1 }}$ removes the receiver or the network from the line. Different circuitry is required for tone and pulse muting external to the IC and applications using both modes would not necessarily share circuitry. MUTE1 timing is shown in Figure 5 for pulse mode signaling and Figure 4 for tone mode signaling.

## HKS

Input. Pin 17. Pin 17 is the hookswitch input to the MK5370. This is a high-impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input causes the on-chip logic to initialize, terminating any operation in progress at the time. The signaling mode defaults to the mode selected at pin 2.

## PULSE OUTPUT

Output. Pin 18. This pin has a dual function determined by the dialing mode selected. In Pulse Mode, the pin is an output consisting of an open drain N channel device with zener protection. The break timing at this output meets Bell Telephone and EIA specifications for loop disconnect signaling. Figure 4 shows this timing.

## DEVICE OPERATION (tone mode)

When the MK5370 is not actively dialing, it consumes very little current. While on-hook, all keypad input pins are pulled high. Key entries are not recognized unless they utilize a keypad common connection to force the respective Row and Column inputs low. These inputs assume opposite states off-hook. The circuit verifies that a valid key has been entered by alternately scanning the Row and Column inputs. If the input is still valid following 32 ms of debounce, the digit is stored into memory, and dialing begins after a pre-signal delay of 100 ms . Each digit buffered into the RAM is dialed out with a 98 ms burst of DTMF and an intersignal time of 102 ms .
One important feature of the dialer is its ability to buffer data into the RAM before signaling. This feature allows less expensive keyboards to be used because signal distortion and double digit entry caused by bouncing and bounding of the keypad are eliminated. This design also ensures that data stored in the buffer exactly matches the digits actually dialed.

NORMAL DIALING (off-hook)

...ETC

Normal dialing is straightforward, all keyboard entries will be stored in the buffer and signaled in succession.

## LAST NUMBER DIALED (LND)

Last number dialing is accomplished by entering the * or \# key as the first entry after coming off-hook.

Table 1 : DTMF Output Frequency.

| Key Input | Standard Frequency | Actual Frequency | $\%$ Deviation |
| ---: | :---: | :---: | :---: |
| ROW 1 | 697 | 699.1 | +0.31 |
| 2 | 770 | 766.2 | -0.49 |
| 3 | 852 | 847.4 | -0.54 |
| 4 | 941 | 948.0 | +0.74 |
| COL 1 | 1209 | 1215.9 | +0.57 |

| 3 | 1477 | 1471.9 | -0.35 |

Figure 4 : Tone Mode Timing.

Figure 5 : Pulse Mode Timing.

Figure 6 : Pulse and Tone Mode Timing.

## TYPICAL APPLICATION

The MK5370 Pulse Tone dialer provides both costeffective telephone-line interface and the logic required for DTMF (Tone) and Loop Disconnect (Pulse) signaling.
Pulse dialing originated with the rotary dial telephone. The MK5370 Pulse Tone dialer provides the same capability as the rotary dial telephone and the convenience of pushbutton entry. The subscriber set (telephone) is powered by loop current supplied by the telephone company. Signaling, in Pulse Mode, is accomplished by repeatedly interrupting the low current. The central office senses, times, and counts each line "break" ; the number of breaks corresponds to the digit dialed. The duration of the break period, the dialing rate, and the separation between consecutive digits (IDP time) are controlled by the Pulse Tone dialer IC. Loop disconnect dialing is nearly a world-standard concept.
DTMF signaling consists of modulating the telephone line with a signal comprised of two fundamental frequencies. Each frequency pair represents one of sixteen possible digit (or key) entries. Twelve of these frequency pairs are commonly used ( $0,1,2$, ...., *, \# ). The MK5370 Pulse Tone dialer provides DTMF signalling capability controlling signal duration, separation, level, and rate.
The typical application circuit in Figure 7 illustrates one way the Pulse Tone dialer can be used. The
pulse output provides the signal to break the line to transistor Q3. Q3 switches off, eliminating the base current to Q4, which also switches off. The majority of the loop current is then eliminated, resulting in a break condition. The IC dialer must be protected from large voltage fluctuations, such as that caused by interrupting the loop current. Transistor Q1 along with R2, C1, and Z1 regulate the voltage to the dialer. The Mute Output signal is active while signalling each digit to mute popping noises at the receiver (earpiece or speaker).
The DTMF tone output drives the base of Q8, which modulates the line. The tone level at tip and ring is determined by the effective impedance of the telephone line and the speech network.
Mode of operation is controlled by switch S1 (which sets the default dialing mode).
Resistor R1 provides a small memory-retention bias current to prevent the device from powering down while on hook. The current required for long term memory retention is less than $1 \mu \mathrm{~A}$.
A ceramic sounder can also be interfaced to pin 11 (PACIFIER TONE) of the device. A pacifier tone signal is activated for each key entry in pulse mode. This feature provides an audible indication for each valid key entry. Keys may be entered faster than the maximum signalling rate allows. Audible feedback confirms proper key entry.

## SINGLE NUMBER PULSE TONE SWITCHABLE DIALER

- STAND-ALONE DTMF AND PULSE SIGNALING
- SOFTSWITCH AUTOMATICALLY SWITCHES SIGNALING MODE
RECALL OF LAST NUMBER DIALED (UP TO 28 DIGITS LONG)
- FLASH KEY INPUT INITIATES TIMED HOOK FLASH
- MICROPROCESSOR INTERFACE (BDC INPUTS) FOR SMART TELEPHONES
- TIMED PABX PAUSE
- FORM-A AND 2-OF-8KEYBOARD INTERFACE
- PACIFIER TONE
- POWERED FROM TELEPHONE LINE, LOW OPERATING VOLTAGE FOR LONG LOOP APPLICATIONS

## DESCRIPTION

The MK5371 is a monolithic, integrated circuit manufactured using Silicon Gate CMOS process. These circuits provide necessary signals for either DTMF or loop disconnect (Pulse) dialing. The MK5371 buffers up to 28 digits into memory that can be later redialed with a single key input. This memory capacity is sufficient for local, long distance, overseas, and even computerized long-haul networks. Users can store all 12 signaling keys and access several unique special functions with single key entries. These functions include : Last Number Dialed (LND), Softswitch (Mode), Flash, and Pause.
A LND key input automatically redials the last number dialed. Keys entered during auto-dialing sequence will not be stored or dialed. However, autodialing is momentarily interrupted (during interdigital pause period or intersignal period) while manual keys are depressed.
The mode key simplifies the process of alternating dialing modes. This input automatically toggles the immediate dialing mode. The function is also stored in memory. During auto-redial, the signaling mode is toggled each time the Mode code appears in the digit sequence. The signaling mode always defaults to the mode selected (hardwire or switch) at Pin 2 (MODE) after a Power-Up-Clear initialization or a transition from on-hook to off-hook (HKS input switched from a high to low logic level). Switching modes

## KEYPAD CONFIGURATION

M88MK53フ1-01
through Pin 2 toggles the immediate dialing mode and changes the default, but it is not stored in memory.
Two features simplify PABX dialing. The pause key stores a timed pause in the number sequence. Redial is then delayed until an outside line can be accessed or some other activity occurs before normal signaling resumes. The Flash key simulates a hook flash to transfer calls or to activate other special features provided by the PABX or a central office. The MK5371 ensures exact timing for the hook flash.
In addition to interfacing with standard keypads, the MK5371 also accepts parallel BCD inputs. This feature simplifies interfacing a microprocessor-based design to the telephone line. The MK5371 buffers 28 bytes of information, including special functions.

PIN CONNECTION

## BLOCK DIAGRAM

## ABSOLUTE MAXIMUM RATINGS

| Parameter | Value | Unit |
| :--- | :---: | :---: |
| DC Supply Voltage | 6.5 | V |
| Operating Temperature | -30 to +60 | ${ }^{\circ} \mathrm{C}$ |
| Storage Temperature | -55 to +125 | ${ }^{\circ} \mathrm{C}$ |
| Maximum Power Dissipation $\left(25^{\circ} \mathrm{C}\right)$ | 500 | mW |
| Maximum Voltage on Any Pin | $(\mathrm{V}+)+0.3,(\mathrm{~V}-)-0.3$ | V |

* Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating onIy and functional operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device rehability.

## ELECTRICAL OPERATING CHARACTERISTICS

(all specifications are for 2.5 Volt operation and full operating temperature range unless otherwise stated)

## DC CHARACTERISTICS

| Symbol | Parameter | Min. | Typ. | Max. | Unit | Notes |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{+}$ | DC Operating Voltage | 2.5 |  | 6.0 | V |  |
| $\mathrm{~V}_{\mathrm{MR}}$ | Memory Retention Voltage | 1.5 |  |  | V | 1,6 |
| $\mathrm{I}_{\mathrm{s}}$ | Standby Current |  | 0.2 | 0.750 | $\mu \mathrm{~A}$ | 1 |
| $\mathrm{I}_{\mathrm{MR}}$ | Memory Retention Current |  | 0,10 | 0.75 | $\mu \mathrm{~A}$ | 5,6 |
| $\mathrm{I}_{\mathrm{T}}$ | Operating Current (tone) |  | 300 | 600 | $\mu \mathrm{~A}$ | 2 |
| $\mathrm{I}_{\mathrm{P}}$ | Operating Current (pulse) |  | 225 | 350 | $\mu \mathrm{~A}$ | 2 |
| $\mathrm{I}_{\mathrm{ML}}$ | Mute Output Sink Current | 1.0 | 2.0 |  | mA | 3 |
| $\mathrm{I}_{\mathrm{PL}}$ | Pulse Output Sink Current | 1.0 | 2.0 |  | mA | 3 |
| $\mathrm{I}_{\mathrm{PC}}$ | Pacifier Tone Sink/Source | 250 | 500 |  | $\mu \mathrm{~A}$ | 4 |
| $\mathrm{~K}_{\mathrm{RU}}$ | Keypad Pullup Resistance |  | 100 |  | $\mathrm{k} \Omega$ |  |

Notes: 1. OdBm equals 1 mW power into 600 ohms ( 775 mVolts ). Important Note : The MK5371 is designed to drive a 10 kohm load. The 600 ohm load is only for reference.
2. Single tone (low group).
3. Supply voltage $=2.5$ to 6 Volts. $R_{E}=10$ kohms.
4. $R_{E}=10 \mathrm{k}$ ohms. $\mathrm{V}_{+}=2.5$ Volts.
5. Supply voltage $=2.5$ Volts. These specifications are supply-dependent.
6. Time from beginning of tone output waveform to $90 \%$ of final magnitude of eitheir frequency. Crystal parameters suggested for proper operation are $R_{S}<100 \Omega . \mathrm{L}_{\mathrm{m}}=96 \mathrm{mH} . \mathrm{C}_{\mathrm{m}}=0.02 \mathrm{pF} . \mathrm{C}_{\mathrm{h}}=5 \mathrm{pF} . \mathrm{f}=3.579545 \mathrm{MHz}$ and $\mathrm{C}_{\mathrm{L}}=18 \mathrm{pF}$.
7. Time from Mute active to beginning of signaling.

## FUNCTIONAL DESCRIPTION

The following pin descriptions are numbered according to the 24 -pin package. Pin numbers for the 18pin version are listed in parenthesis under each pin name.

## V+

Pin 1. $V_{+}$is the positive supply for the circuit and must meet the maximum and minimum voltage requirements. (see Electrical Specifications).

## MODE

Input. Pin 2. MODE determines the dialer's default operating mode. When the device is powered up or the hookswitch input is switched from on-hook, ( $\mathrm{V}+$ ), to off-hook, ( $\mathrm{V}-$ ), the default determines the signaling mode. A V+connection defaults to Tone Mode operation and a V-.connection defaults to Pulse Mode operation.

A Softswitch (Mode) code entered in a number sequence can temporarily modify the signaling mode. After encountering a first Softswitch code in a number sequence, the Signaling Mode toggles and is opposite the default determined by Pin 2. A second Softswitch toggles the Signaling Mode a second time, returning the mode back to the default condition. Note that the Softswitch code performs a toggle function on the default state; switching the state of Pin 2 while dialing changes the default state as well as the immediate signaling mode.
$\overline{\mathrm{C} 1} / \mathrm{STROBE}, \overline{\mathrm{C} 2}, \overline{\mathrm{C} 3}, \overline{\mathrm{C} 4}, \overline{\mathrm{R} 4}, \overline{\mathrm{R} 3}, \overline{\mathrm{R} 2}, \overline{\mathrm{R} 1}$
Keyboard input. Pins 3, 4, 5, 9, 13, 14, 15, 16. The MK5371 interfaces with standard keypads as well as a microprocessor-driven 4-bit bus.
A valid keypad entry is either a single Row connected to a single Column or V- simultaneously presented to both a single Row and Column. In its quiescent or standby state, during normal off-hook operation, either the Rows or the Columns are at a logic level $1(\mathrm{~V}+$ ). Pulling one input low enables the on-chip oscillator. Keyboard scanning then begins. Scanning consists of Rows and Columns alternately switching high through on-chip pullups. After both a Row and Column key have been detected, the debounce counter is enabled and any noise (boucing contacts, etc.) is ignored for a debounce period (Tdb) of 32 ms . At this time, the keyboard is sampled and if both Row and Column information is valid, the information is buffered into the LND location. If switched on-hook, the keyboard inputs all pull high through on-chip pull-up resistors. Information may still be entered into memory but it is not signaled and the keyboard scan is disabled. If users desire to enter data while on-hook, a 2-of-8 keypad with negative common is required.
A key entry during LND interrupts the sequence when it reaches the redial period until the key is released. Dialing then resumes. The key entered is not stored or dialed.

The keyboard inputs become high impedance when the Binary Input Mode is selected. As shown in Table 1, Row pins become inputs for the Binary codes from a microprocessor in this mode. Table 1 equates the Binary Codes to the keyboard digits and special functions. The C1 input pin now provides an input for a strobe strobe used to clock the valid codes into the LND buffer. Dialing proceeds at the specified rates. The strobe duration must be active for at least $2 \mu$ s to ensure proper acceptance of the information. If the strobe remains high for longer than 96 ms false dialing may occur. A minimum of 8 ms must separate each strobe. Figure 1 illustrates the required strobe/data timing. Valid encoded signaling information must be present until the strobe goes low. Information entered during an on-hook operation is stored but signaling is inhibited. Changing between BCD and keyboard mode can only occur when the HKS input is high, or upon power-up. Caution, a power supply transient may be interpreted as a power-up condition, and the logic level on pin 11 at that time will be interpreted as a valid BCD/Keyboard selection.

## V-

Input. Pin 6. Pin 6 is the negative supply input to the device. This is the voltage reference for all specifications.

## OSC1, OSC2

Input/Output. Pins 7, 8. OSC1 and OSC2 are inputs to an on-chip inverter used as the timing reference for the circuit. It has sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation from this standard is directly reflected in the Tone output frequencies. The crystal oscillator provides the time reference for all circuit functions.

## DTMF OUTPUT

Output. Pin 10. An NPN transistor emitter with a collector tied to V+ drives the DTMF OUTPUT pin. The transistor base is connected to an on-chip operational amplifier that mixes the Row and Column Tones together. Figure 4 shows the timing at this pin.

## PACIFIER TONE OUTPUT/BCD MODE

Input/Output. Pin 11. A 500 Hz square wave is activated at this pin upon acceptance of a valid key input, after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. In the Pulse mode the PACIFIER TONE is activated for all key entries. The PACIFIER TONE provides audible feedback, confirming that the key has been properly entered and accepted. In Tone mode, only the LND key ac-

Figure 2 : Single Tone.
 tivates the PACIFIER TONE.

This pin is normally high impedance until a key is entered. Connecting this pin high through a resistor causes the circuit to accept BCD inputs through the

Figure 3 : Dual Tone.

Figure 4 : Spectral Reponse.

Figure 5 : Tone Mode Timing.

ROW pins. In Biṇary Mode, as mentioned in the keyboard interface description, the keyboard inputs are all high impedance. Keypad inputs in this mode are not recognized. Connecting this pin low enables the keyboard scan circuitry, which allows entries. The mode of operation is selected upon power-up, and thereafter may only occur when HKS pin 17 is high.

## MUTE1

Output. Pin 12. This pin is the Mute Output for both Tone and Pulse Modes. Timing is dependent upon mode.
The output consists of an open drain N -channel device. During standby, the output is high impedance and generally has an external pullup resistor to the positive supply.
In Tone Mode, MUTE1 removes the transmitter and the receiver from the network during DTMF signaling. During dialing, MUTE1 is active continuously until dialing is completed.
In Pulse Mode, MUTE1 removes the receiver or the network from the line. Different circuitry is required for Tone and Pulse muting external to the IC and applications using both modes would not necessarily share circuitry. MUTE1 timing is shown in Figure 6 for Pulse Mode signaling and Figure 5 for Tone Mode signaling.

## HKS

Input. Pin 17. Pin 17 is the hookswitch input to the MK5372. This is a high impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input causes the on-chip logic to initialize, terminating any operation in progress at the time. The signaling mode defaults to the mode selected at Pin 2.

## PULSE OUTPUT

Output. Pin 18. This pin has a dual function determined by the dialing mode selected. In Pulse Mode, the pin is an output consisting of an open drain N channel device with zener protection. The break timing at this output meets Bell Telephone and EIA specifications for loop disconnect signaling. The Make/Break ratio is not user selectable in the 18-pin version. PULSE OUTPUT also provides the break timing for the hook flash function. Figure 6 shows this timing.

## DEVICE OPERATION (Tone Mode)

When the MK5371 is not actively dialing, it consumes very little current. While on-hook, all key-
pad input pins are pulled high. Key entries are not recognized unless they utilize a keypad common connection to force the respective Row and Column inputs low. These inputs assume opposite states off-hook. The circuit verifies that a valid key has been entered by alternately scanning the Row and Column inputs. If the input is still valid following 32 ms of debounce, the digit is stored into memory, the Mute Output is activated, and dialing begins after a pre-signal delay of 100 ms . Each digit buffered into the RAM is dialed out with a 98 ms burst of DTMF and an intersignal time of 102 ms .
One important feature of the dialer is its ability to buffer data into the RAM before signaling. This feature allows less expensive keyboards to be used because signal distortion and double digit entry caused by bouncing and bounding of the keypad are eliminated. This design also ensures that data stored in the buffer exactly matches the digits actually dialed.

NORMAL DIALING (off-hoof)

Normal dialing is straightforward, all keyboard entries will be stored in the buffer and signaled in succession.

## LAST NUMBER DIALED (LND)

Last Number Dialing is accomplished by entering the LND key.

## PABX PAUSE

A pause may be entered into the dialed sequence at any point by keying in the special function key, Pause. Pause inserts a 1.1-second delay into the dialing sequence. The total delay, including pre-digital and post-digital pauses is shown in Table 3.

## HOOK FLASH

D FLASH D ....ETC

HOOK FLASH may be entered into the dialed sequence at any point by keying in the function key, Flash. The flash function is stored in the LND buffer just like any other digit, but it will not be redialed, and acts much like Pause. The MK5371 has a HOOK FLASH time of 600 ms .

## SOFTSWITCH

Softswitch allows the user to easily switch from Pulse to Tone Mode while dialing a number sequence. For example, the first digits may be entered in Pulse Mode. Signaling will proceed in Pulse Mode until a Softswitch (Mode) entry is encountered. Any subsequent digits are dialed using DTMF signals. A hookswitch transition or a second Softswitch entry returns dialing to the original Default Mode.
Each special function provides a built-in delay before auto-dialing resumes. The fixed delay introduced by the function is 1.1 seconds. In addition, the fixed delay is preceded and followed by the standard interdigital pause period that depends on the selected signaling mode. Table 3 lists the actual delays produced by each function.

Table 3 : Special Function Delay Periods.

| Function | Delay | Pulse Mode | Tone Mode |
| :--- | :---: | :---: | :---: |
| PAUSE | IDP + 1.1 + IDP | + IDP | 1.5 sec |

Figure 6 : Pulse Mode Timing.

Figure 7 : Pulse And Tone Mode Timing.

## TYPICAL APPLICATION

The MK5371 Pulse Tone dialer provides both costeffective telephone-line interface and the logic required for DTMF (Tone) and Loop Disconnect (Pulse) signaling.
Pulse dialing originated with the rotary dial telephone. The MK5371 Pulse Tone dialer provides the same capability as the rotary dial telephone and the convenience of pushbutton entry. The subscriber set (telephone) is powered by loop current supplied by the telephone company. Signaling, in Pulse Mode, is accomplished by repeatedly interrupting the loop current. The central office senses, times, and counts each line "break" ; the number of breaks
corresponds to the digit dialed. The duration of the break period, the dialing rate, and the separation between consecutive digits (IDP time) are controlled by the Pulse Tone dialer IC. Loop disconnect dialing is nearly a world-standard concept.
DTMF signalling consists of modulating the telephone line with a signal comprised of two fundamental frequencies. Each frequency pair represents one of sixteen possible digit (or key) entries. Twelve of these frequency pairs are commonly used ( $0,1,2$, ....,*, \#). The MK5371 Pulse Tone dialer provides DTMF signalling capability controlling signal duration, separation, level, and rate.

The typical application circuit in Figure 8 illustrates one way the Pulse Tone dialer can be used. The pulse output provides the signal to break the line to transistor Q3. Q3 switches off, eliminating the base current to Q4, which also switches off. The majority of the loop current is then eliminated, resulting in a break condition. The IC dialer must be protected from large voltage fluctuations, such as that caused by interrupting the loop current. Transistor Q1 along with $\mathrm{R} 2, \mathrm{C} 1$, and $\mathrm{Z1}$ regulate the voltage to the dialer. The Mute Output signal is active while signalling each digit to mute popping noises at the receiver (earpiece or speaker).
The DTMF tone output drives the base of Q8, which modulates the line. The tone level at tip and ring is determined by the effective impedance of the telephone line and the speech network.

Mode of operation is controlled by switch S1 (which sets the default dialing mode) and the keypad. A change of dialing mode with a Mode (Softswitch) key input is stored in memory and will be repeated when the LND (last number dialed) feature is activated.
Resistor R1 provides a small memory-retention bias current to prevent the device from powering down while on hook. The current required for long term memory retention is less than $1 \mu \mathrm{~A}$.
A ceramic sounder can also be interfaced to pin 11 (BCD/PACIFIER TONE) of the device. A pacifier tone signal is activated for each key entry. This feature provides an audible indication for each valid key entry. Keys may be entered faster than the maximum signalling rate allows. Audible feedback confirms proper key entry.

Figure 8 : MK5371 Typical Application.

SGS-THOMSON

## TEN-NUMBER REPERTORY TONE/PULSE DIALER

- CMOS TECHNOLOGY PROVIDES LOWVOLTAGE OPERATION
- CONVERTS PUSH-BUTTON INPUTS TO BOTH DTMF AND LOOP-DISCONNECT SIGNALS
- STORES TEN 16-DIGIT TELEPHONE NUMBERS, INCLUDING LAST NUMBER DIALED
- PACIFIER TONE AND PBX PAUSE
- LAST-NUMBER-DIALED (LND) PRIVACY
- MANUAL AND AUTO-DIALED DIGITS MAY BE CASCADED
- ABILITY TO STORE AND DIAL BOTH "*" AND "\#" DTMF SIGNALS
- VARIABLE DIALING RATE
- ON-CHIP POWER-UP-CLEAR GUARANTEES DATA INTEGRITY

## DESCRIPTION

The MK5375 is a monolithic, integrated circuit manufactured using Silicon Gate CMOS process. This circuit provides the necessary signals for either DTMF or loop disconnect dialing. It also allows for the storage of ten telephone numbers, including as many as 16 digits each, in on-chip memory.
The MK5375 accepts rapid keypad inputs (up to 25 key entries per second) and buffers these inputs in the FIFO (First-In-First-Out) LND (Last-NumberDialed) register. Each digit entry is accompanied by a pacifer tone. Which is activated after the digit has been debounced, decoded, and properly stored. Si gnaling occurs at a rate determined by externally connected components, allowing the dialing rate to be adjusted for any system.

The flexibility of the dialer makes possible a variety of applications, such as "scratchpad" number storage. In "scratchpad" applications, the MK5375 inhibits signaling during entry, without interrupting a conversation.
Privacy is also an important feature. The MK5375 allows the LND (Last-Number-Dialed) buffer to be cleared following a call, without affecting data stored in other permanent memory locations. The memory in the permanent locations may be easily protected from inadvertent key entries with the addition of a simple "memory lock" switch to the application.
All of these options plus additional features are discussed in more detail in the following sections. the first section contains a brief detailed description of each pin function. The second section describes the device operation. This is followed by the DC and AC Electrical Specifications, and a few application suggestions.

PIN CONNECTION

## BLOCK DIAGRAM

## FUNCTIONAL DESCRIPTION

## $\mathrm{V}+(\mathrm{pin} 1)$

Pin 1 is the positive supply for the circuit and must meet the maximum and minimum voltage requirements as stated in the electrical specifications.

## MODE SELECT (pin 2)

In normal operations. Pin 2 determines the signaling mode used : a logic level $1(\mathrm{~V}+$ ) selects Tone Mode operation. While a logic level $0(\mathrm{~V}-)$ selects Pulse Mode operation. This input must be tied to one of the supplies to guarantee proper dialing.
KEYBOARD INPUT : $\overline{\mathrm{COL}}, \overline{\mathrm{COL} 2}, \overline{\mathrm{COL} 3}, \overline{\mathrm{ROW} 4}$, ROW3, ROW2, ROW1 (pins 3, 4, 5, 13, 14, 15, 16)
The MK5375 keypad interface allows either the standard 2-of-7 keyboard with negative common or the in-expensive single-contact (FORM-A) keyboard to be used (Figure 1). A valid key entry is de-
fined by either a single Row being connected to a single Column or by $\mathrm{V}^{\top \mathrm{M}}$ being presented to both a single Row and Column. In standby mode either all the rows will be a logic $1^{( }\left(V_{+}\right)$and all the columns will be a logic $0(\mathrm{~V}-)$ or vice versa.
The keyboard interface logic detects when an input is pulled low and enables the RC (Rate Control) oscillator and keypad scan. Scanning consists of alternately strobing the rows and columns high through on-chip pullups. After both valid row and column key closures have been detected, the debounce counter is enabled.
Breaks in contact continuity (bouncing contacts, etc.) are ignored for a debounce period ( $\mathrm{T}_{\mathrm{db}}$ ) of $32 . \mathrm{ms}$. At this time the keypad is sampled, and if both row and column information is valid, this information is buffered into the LND location.

Figure 1 : Keypad Schematics.

## RATE CONTROL (pin 7)

The Rate Control input is a single-pin RC oscillator. An external resistor and capacitor determine the rate at which signaling occurs is both Tone and Pulse modes. An 8 kHz oscillation provides the nominal signaling rates of 10 PPS (Pulses per second) in Pulse Mode and 50 TPS (Tones per second) in Tone Mode ; the Tone duty cycle is 98 ms on, 102 ms off. The RC values on this input can be adjusted to a maximum oscillation frequency of 16 kHz resulting in an effective-Pulse rate of 20 PPS an a Tone rate or 10 TPS.
The frequency of oscillation is approximated by the following equation :

Fosc $=1 /(1.49 R C)$
The value suggested for the capacitor (C) should be a maximum of 410 pF to guarantee the accuray of the oscillator. The resistor is then selected for the desired signaling rate. Nominal frequency ( 8 kHz ) is achieved with component values of 390 pF and 220 kohms. Parasitics must be taken into account.

## OSCIN, OSCOUT (pins 8, 9)

Pins 8 and 9 are the input and output, respectively, of an on-chip inverter with sufficient loop gain to oscillate when used in conjunction with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz , and any deviation from
this standard is directly reflected in the Tone Output frequencies.
This oscillator is under direct control of the repertory dialer and is enabled only when a tone signal is to be transmitted. During all other times it remains off, and the input has high impedance. The input OSCIN may be driven by an external source.

## DTMF OUTPUT (pin 10)

The DTMF Output pin is connected internally to the emitter of an NPN transistor, which has its collector tied to $\mathrm{V}_{+}$, as shown on the functional block diagram.
The base of this transistor is the output of an on-chip operational amplifier that mixes the Row and Column Tones together.
The level of the DTMF Output is the sum of a single row frequency and a single column frequency. A typical single-tone sine wave is shown in Figure 2. This waveform is synthesized using a resistor tree with sinusoidally weighted taps.
The tone level of the MK5375 is a function of the supply voltage. The voltage to the device may be regulated to achieve the desired tone level, which is related to the supply by either of the following equations:

$$
\begin{align*}
& \mathrm{T}(0)=20 \mathrm{LOG}[(0.078 \mathrm{~V}+) / 0.775] \mathrm{dBm}  \tag{2.0}\\
& \mathrm{~T}(0)=0.078(\mathrm{~V}+) \text { VRMS. (row tones) } \tag{2.1}
\end{align*}
$$

## PACIFIER TONE OUTPUT / CHIP DISABLE (pin 11)

This pin normally has high impedance. Upon acceptance of a valid key input, and after the 32 ms debounce time, a 500 Hz square-wave will be output on this pin. The square-wave terminates after a maximum of 30 ms or when the valid key is no longer present. The purpose of this pacifier tone is to provide to the user audible feedback taht a valid key has been entered. This feature is useful particularly for on-hook storage and pulse-mode signaling.
The pacifier tone is not enabled when manually dialing in tone mode. this eliminates any confusion between the audible DTMF feedback and the pacifier tone, and prevents distortion of the DTMF signal by any of the pacifier tone frequency components. In both cases, the tone confirms that the key has been properly entered and accepted : whereas without the tone the user will not know if the keys have been properly entered.
IMPORTANT : This pin also serves as a chip-disable pin. pulling this input high through a resistor will disable the keypad (high impedance) and initialize all counters and flip-flops (memory remains undisturbed). Pulling the input low through the same resistor enables the circuit. For the device to function properly, the resistor to V - (pin ) is required.
This feature is useful in several applications, as described in the application notes section.

Figure 2A : Typical Sine Wave Output - Single Tone.

## MUTE OUTPUT (pin 12)

This pin is the Mute output for both.Tone and Pulse modes of operation. The timing is dependent upon which mode is being used. The output consists of an open-frain, N -channel device. During stanby, the output has high impedance and generally requires an external pullup resistor to the positive supply. In Tone Mode, the Mute output is used to remove the transmitter and the receiver from the network during DTMF signaling. The output will mute continuously while auto-dialing and during manual DTMF signaling until each digit entered has been signaled. In Pulse Mode of operation, the Mute output is used to remove the receiver or even the entire network from the line. These timing relation ships are shown in Figure 4.

## HKS INPUT (pin 17)

This pin is a high-impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input will cause the on-chip logic to initialize, terminating any operation in progress at the time. Signaling is inhibited while on-hook, but key inputs will be accepted and stored in the LND register. The information stored in the LND register may be copied into an alternate location only whil on-hook. A logic level may be presented to this input, independent of the position of the hook-switch, allowing on-hook operations, such as storage, to be performed off-hook.

Figure 2B : Typical Dual-tone Waveform
(Row 1, Col 1).

Table 1 : Output Frequency.

| Key <br> Input | Standard <br> Frequency | Actual <br> Frequency | $\%$ <br> Deviation |
| ---: | :---: | :---: | :---: |
| ROW 1 | 697 | 699.1 | +0.31 |
| 2 | 770 | 766.2 | -0.49 |
| 3 | 852 | 847.4 | -0.54 |
| 4 | 941 | 948.0 | +0.74 |
| COL 1 | 1209 | 1215.9 | +0.57 |
| 2 | 1336 | 1331.7 | -0.32 |
| 3 | 1477 | 1471.9 | -0.35 |

## PULSE (pin 18)

This is an output driven by an open-drain, N -channel device. In Pulse Mode operation, the timing at this output meets Bell Telephone and EIA specifications for loop-disconnect signaling. The Make/Brake ratio is set to $40 / 60$ on the standard MK5375. The pulse rate is determined By the RC values selected for the Rate Control, Pin 7. Note : The standard make/break ratio may not be suitable if the Pulse dialing rate is accelerated.

## DEVICE OPERATION

The Mk5375 can be used in low-priced phones with basic $3 \times 4$ matrix keypads. the block diagram shows the data and control signal flow between the various functional blocks. The keypad entries are decoded, debounced, and if valid, they are stored into the LND
(Last-Number-Dialed) buffer, which acts much like a FIFO (First-In-First-Out) register. Each subsequent entry is stacked in the buffer. Typically, the dialing sequence begins 172 ms after the first digit is accepted in Pulse Mode operation and 132 ms in Tone Mode operation. Each digit buffered into the RAM is dialed out with a 98 ms burst of DTMF and an inter-signal time of 102 ms .
Buffering the data into the RAM prior to signaling is an important feature of the repertory dialer. It allows for the use of less expensive keypads, since the user cannot enter the digits too quickly for the system, and the pacifier tone can be used to provide audible feedback following each key entry not generating a DTMF signal. It also guarantees that the data stored in the RAM matches exactly the digits actually dialed.
Manual dialing and auto-dialing can be executed in any order, consecutively or cascaded. The dialer must complete auto-dialing the previous entry before another key is entered. Digits should not be entered while the device is auto-dialing. Most digits would be ignored unless preceded by a control key: in which case, an error in dialing may occur.
Figure 3 : Keypad Configuration.

| 1 | 2 | 3 |
| :---: | :---: | :---: |
| 4 | 5 | 6 |
| 7 | 8 | 9 |
| STORE <br> DIAL | $\begin{gathered} 0 \\ \text { LND } \end{gathered}$ |  |

## NORMAL DIALING

The "*".(STAR) key is used as the modifier to control repertory functions. All numeric keys will signal normally unless preceded by a modifier. To signal ei: ther a "*" or "\#", these keys must be entered twice in succession. The first entry is not signaled or stored.

## LND PRIVACY

A single "*" input prior to going on-hook or prior to coming off-hook will erase the information stored in the LND buffer.
AUTO DIALING (off-hook)

The key sequence "*" followed by any digit, will autodial the number sequence stored in the designated address location while off-hook.

STORAGE (on-hook)
$\mathbf{D}$ D $\mathbf{D}$ D $\mathbf{N}$
$D$ is any data (telephone numbers) being entered or dialed. $N$ is the address (memory location) in which numbers are stored. The number sequence stored in the LND buffer can be transfered to one the other
nine permanent locations whith the simple sequence "*" followed by the address. New digits may be written into the LND buffer while on-hook. To enter either a "*" or "\#" signal the digit must be entered twice in succession.

PABX PAUSE (off-hook and on-hook)
$\mathbf{D} \square \mathbf{D} \square \mathbf{D}$

An indefinite pause is stored in a number sequence by entering the "*" key modifier, followed by a"\#" key input. When the number sequence is redialed, the dialer will pause when it encounters the "\#" entry. A key input will cause it to continue.

## PULSE DIALING

Most of the Pulse key operations are the same as they were in Tone Mode ; PABX Pause is the only exception. In Pulse Mode, the pause may be stored as in tone mode, "* \#", or with a single "\#" inputs will store two pauses.
The "*" key exercises the control function ; two "*" inputs will be the same as a single input (multiple inputs are not accepted).

Notes: 1. Typical time assume nominal RC input frequency of 8 kHz . An increase in frequency results in an equal decrease in time values and an equal increase in rate values.

## APPLICATION CIRCUIT

The MK5375 integrated circuit provides the ability to convert keypad inputs into either DTMF or loopdisconnect signals compatible with most telephone systems. Both modes of signaling utilise loop currents to transmit the desired signaling information to the central office.
The circuit schematic in Figure 5 illustrates a typical implementation of the MK5375 dialer IC along with the necessary components required to interface with the telephone line in a tone/pulse application.
In loop-disconnect signaling, each digit dialed consists of a series of momentary interruptions of loop current called "breaks" (i.e., a digit "1" consists of a single break, a digit "2" consists of two breaks, and so on. The Pulse output is dedicated to loopdisconnect signaling and controls the flow of loop current through the speech network switching transistors, Q4 and Q5. The Mute output, through transistors Q2 and Q3, removes the receiver and transmitter to eliminate loud pops in the receiver caused by switching current through the network. The Pulse and Mute output signals, as shown in Figure 4A, consist of make, break, and interdigital time intervals.
DTMF signaling requires that the loop current be modulated, producing an analog signal on the telephone line. Transistor Q1 modulates the loop current by amplifying the DTMF signal coupled to its base from the Tone Output. The Mute output removes the receiver and transmitter by switching transistors Q2 and Q3. This eliminates any interference with the DTMF signal from the transmitter and cuts down on the amplitude of the DTMF tone heard at the receiver. The timing diagram in Figure 4B illustrates the time relationship between key entries, Tone Output, and Mute Output.
The voltage regulator circuit comprising resistor R2, zener diode Z2, and transistor Q6 serves several purposes. In tone mode operation, it provides the regulated supply voltage to the MK5375 which determines the DTMF signal amplitude at the Tone Output. Varying the supply voltage will vary the DTMF output signal. In pulse mode, it helps provide
some isolation from the transients caused by switching the speech network in and out.
During normal off-hook dialing, the MK5375 operates using current from the telephone line. On-hook number storage and memory retention current are supplied by the battery shown in Figure 5. Transistor Q6 prevents the flow of battery current to the speech network.
The rate at which dialing occurs is determined by the values chosen for resistor R1 and capacitor C1. These values can be predetermined using equation (1.0) described above. The 3.5795 MHz crystal is used as a reference for systhesizing the DTMF signals and is activated only for the short periods during which these tones are being generated.
The application circuit schematic in Figure 6 gives an example of the various features which can be utilized with the addition of several switches. the example also shows that multiple devices may be used to increase the effective storage capability of the telephone design.
Much of the circuity used to modulate and pulse the line, mute the speech network, and regulate the supply voltage is unchanged from the basic tone/pulse switchable telephone described above.
The two devices in Figure 6 are hooked up in parallel with on another except for their oscillator pins and the Chip Disable inputs. A DPDT switch is used to select between the two dialers through the Chip Disable pin ; one device is activated while the other is put on standby.
Some applications may include a memory lock switch to prevent any of the data stored to be changed inadvertently. This memory lock switch can take the form of a locking key switch, which would allow only the person with the key to alter data stored in memory.
A scratchpad feature may be implemented to allow off-hook programmming of the memory while inhibiting dialing. A switch is added in series with the telephone hook-switch to allow the dialer to be forced into its on)hook key entry mode while the telephone set is off-hook.

## TEN-NUMBER REPERTORY TONE/PULSE DIALER

- CONVERTS PUSH-BUTTON INPUTS TO BOTH DTMF AND PULSE SIGNALS
- STORES TEN 16-DIGIT TELEPHONE NUMBERS INCLUDING LAST NUMBER DIALED
- PACIFIER TONE AND PBX PAUSE
- LAST NUMBER DIALED (LND) PRIVACY
- MANUAL AND AUTO-DIALED DIGITS MAY BE CASCADED
- ABILITY TO STORE AND DIAL BOTH * AND \# DTMF SIGNALS

## DESCRIPTION

The MK5376 is a monolithic, integrated circuit manufactured using Silicon Gate CMOS process. This circuit provides the necessary signals for either DTMF or loop disconnect dialing. Ten telephone numbers of up to 16 digits each may be stored in the on-chip RAM. Manual and auto-dialed numbers may be cascaded in any order.
Additional functions available are a Pacifier Tone output, PABX pause, external control of the signaling rate, and total functional control with either a standard $3 \times 4$ matrix keypad (FORM-A) or a 2-of-7 keyboard. A 13th key option allows control of the dialer's repertory features. The telephone keypad

then functions for signaling purposes only, independent of the repertory functions. The 13th key mode and the M-B (Make/Break) Ratio is user selectable.
The dialer's flexibility provides for many applications, for example, off-hook programming, the use of additional chips in parallel for 10,20, and 30 number repertory phones, permanent memory protection and the option of a supply-independent or sup-ply-dependent tone level.

## PIN CONNECTION

## FUNCTIONAL DESCRIPTION

V+
Pin 1. Pin 1 is the positive supply for the circuit and must meet the voltage requirements defined in the Electrical Specifications.

## MODE SELECT

Input. Pin 2. In normal operation, Pin 2 determines the Signaling Mode; a logic level 1 ( $\mathrm{V}+$ ) selects Tone Mode, while a logic level 0 (V-) selects Pulse Mode operation. To guarantee proper dialing, this input must be tied to one of the supplies.

## $\overline{\mathrm{COL}}, \overline{\mathrm{COL} 2}, \overline{\mathrm{COL} 3}, \overline{\mathrm{ROW} 4}, \overline{\mathrm{ROW} 3}, \overline{\mathrm{ROW} 2}$, ROW1

Keyboard Input. Pins 3, 4, 6, 18, 19, 20, 21. The MK5376 keypad interface allows users to add either the standard 2-of-7 keyboard with negative common or the inexpensive single-contact (Form-A) keyboard (see Figure 1). A valid key entry is either a single Row connected to a single column or V-presented to both a single Row and Column. In Standby Mode, either all the Rows pull to a logic 1 (V+) and all the Columns are a logic 0 or vice versa.
The keyboard interface logic detects an input being pulled low and enables the RC (RATE CONTROL) oscillator and keypad scan. Scanning consists of Rows and Columns alternately strobing high through on-chip pullups. After both a valid Row and Column key closure have been detected, the debounce counter is enabled Breaks in contact continuity (bouncing contacts, etc.) are ignored for a debounce period (Tdb) of 32 ms . At this time, the key-
pad is sampled. If both Row and Column information is valid, this information is buffered into the LND.

## V-

Input. Pin 7. This pin is the negative supply input to the device. This is the voltage reference for all specifications.

## RATE CONTROL

Input. Pin 9. RATE CONTROL is a single-pin RC oscillator. An external resistor and capacitor determine signaling rates in both Tone and Pulse Modes. An 8 KHz oscillation provides nominal signaling rates of 10 PPS (pulses per second) in Pulse Mode and
Figure 1A : Keyboard Schematics-Calculator Type Keypad.

Figure 1B : Keyboard Schematics Standard Telephone Type Keypad.

5 TPS (tones per second) in Tone Mode ; the tone duty cycle is 98 ms on, 102 ms off. RC values on this input can be adjusted to a maximum oscillation frequency of 16 KHz , resulting in an effective Pulse rate of 20 PPS and Tone rate of 10 TPS.
The following equation approximates the oscillation frequency:

$$
\text { Fosc }=1 /(1.49 R C)
$$

The capacitor's (C) suggested value should be a maximum of 410 pF to guarantee accuracy of the oscillator. The resistor (R) is then selected for the desired signaling rate. The nominal frequency of 8 kHz is achieved with component values of 390 pF and 220 K ohms.

## OSC1, OSC2

Input/Output. Pins 10,11. Pins 10 and 11 are the input and output, respectively, of an on-chip inverter. They have sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation is directly reflected in the Tone Output frequencies.
The repertory dialer directly controls the oscillator and is only enabled for tone signal transmission. It remains off at all other times and the input is high impedance. An external source may also drive the input.

## TONE LEVEL SELECT

Input. Pin 12. The MK5376 has selectable tone levels with supply-independent or supply-dependent specifications. The tone levels available are similar to those provided on Mostek's industry standard MK5380 and MK5089 DTMF generators (see Table 1). The optimum tone scheme is application-dependent.
Table 1 : Tone Level Select.

| Tone Level <br> Select Input | Tone Reference | Compatible <br> With |
| :---: | :---: | :---: |
| V - (method 1) | Supply | MK5089 |
| $\mathrm{V}+$ (method 2) | On-chip Reference | MK5380 |

Method 1 operates from a regulated supply. The tone level is related to this supply by either of the following equations :

$$
\begin{gathered}
\mathrm{To}=20 \mathrm{LOG}[0.0776(\mathrm{~V}+) / 0.775] \mathrm{dBm} \\
\mathrm{To}=0.0776(\mathrm{~V}+) \mathrm{Vrms}
\end{gathered}
$$

Method 2 provides a constant tone output and modulates its own supply in a minimum parts count configuration. The tone level, when used in a subscriber set, is a function of the output resistor $R_{E}$ and
the telephone AC resistance RL. The low-group single tone output amplitude is a function of $R_{E}$ and $R_{L}$ described by the equation :

$$
\left.V_{O}=\left\{1 /\left[0.2+R_{E}\right) / R_{L}\right]\right\} T_{O}
$$

where $V_{0}$ is the tone amplitude at the phone line and To is the tone level at the DTMF OUTPUT pin. This version may also be operated on a regulated supply, but users must observe additional caution to prevent signal distortion (clipping) on longer loops.

## M/B SELECT

Input. Pin 13. In Pulse Mode, this pin selects the Make/Break ratio, or the percentage Break time per Pulse period (see Table 2).
Table 2 : Make/Break Ratio.

| M-B Select <br> Input | Break Time | Make Time |
| :---: | :---: | :---: |
| $\mathrm{V}^{+}$ | 68 | 32 |
| $\mathrm{~V}^{2}$ | 60 | 40 |

Figure 2 : Typical Sine Wave Output.

## DTMF OUTPUT

Output. Pin 14. The DTMF OUTPUT pin is connected internally to an NPN transistor's emitter with a collector tied to $\mathrm{V}_{+}$. The transistor base is the output of an on-chip operational amplifier that mixes the Row and Column Tones together.
The DTMF OUTPUT level is the sum of a single Row single tone sine wave is shown in Figure 2. This waveform is synthesized using a resistor tree with sinusoidally weighted taps. DTMF output frequencies are defined by Table 3.

## PACIFIER TONE OUTPUT/CHIP DISABLE

Input/Output. Pin 15. A 500 Hz square wave is output on this pin after acceptance of a valid key input
and after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. The PACIFIER TONE audibly signals a valid key entry. This feature is particularly useful for on-hook storage and Pulse Mode signaling. The PACIFIER TONE is not enabled when users manually dial in Tone Mode. This eliminates any confusion between the audible DTMF feedback and the PACIFIER TONE. In both cases, the tone confirms that the key has been properly entered and accepted. Without the tone, users do not know if the keys have been properly entered.
This pin is normally high impedance until a key is entered. It also serves as a CHIP DISABLE pin. Pulling this input high through a resistor disables the keypad (high impedance) and initializes all counters and flip flops (memory remains undisturbed). Pulling the input low through the same resistor enables the circuit.
This feature is useful in several applications. It provides a convenient way to lock memory by connecting this input through a resistor to HKS. When it is
on-hook, the device is then disabled and key inputs are not recognized. The circuit will function normally off-hook. Information can only be entered into the permanent memory locations by switching to Program Mode. This requires that a switch and resistor be added to connect to $\mathrm{V}-$.

## MUTE

Output. Pin 16. This pin is the mute output for both Tone and Pulse Modes. Timing depends on which mode is used.
The output consists of an open drain N -channel device and zener input protection. During standby, the output is high impedance and generally requires an external pullup resistor to the positive supply.
In Tone Mode, MUTE removes the transmitter and receiver from the network during DTMF signaling. The output then mutes continuously while auto-dialing and during manual DTMF signaling.
In Pulse Mode, the MUTE removes the receiver or even the entire network from the line. Timing is avai-

Table 3 : Output Frequency.

| Key Input | Standard Frequency | Actual Frequency | \% Deviation |
| :---: | :---: | :---: | :---: |
| ROW 1 | 697 | 699.1 | +0.31 |
| 2 | 770 | 766.2 | -0.49 |
| 3 | 852 | 847.4 | -0.54 |
| 4 | 941 | 948.0 | +0.74 |
| COL 1 | 1209 | 1215.9 | +0.57 |
| 2 | 1336 | 1331.7 | -0.32 |
| 3 | 1477 | 1471.9 | -0.35 |

Figure 3A : MK5376 Timing Diagram - Pulse Mode Off-Hook Operation.

Figure 3B : MK5376 Timing Diagram - Tone Mode.

lable both as a continuous mute (provided by the MK5376) or a mute that is active only when actually pulsing the line. Figure 3 depicts these timing relationships.

## HKS

Input. Pin 22. This pin is a high impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input initializes the on-chip logic. This stops the current operation. A logic level independent of the hookswitch position may be presented to this input, which allows on-hook operations, such as storage, to be performed off-hook.

## 13KEY

Input. Pin.23. This pin is a high impedance input. When it is tied permanently low, it indicates 12KEY Mode. If users desire 13KEY operation, a switch to the negative supply is attached to this pin, along with an external pullup. This forces the repertory dialer into 13KEY Mode. The dialer switches to 12KEY mode if users depress the 13th key switch while simultaneously entering information through the keypad. The differences between these modes are presented in the Device Operation Section.

## PULSE OUTPUT

Output. Pin 24. An open drain N-channel device drives this pin. In Pulse Mode, the timing meets Bell Telephone and EIA specifications for loop disconnect signaling. The Make/Break ratio is user-selectable. RATE CONTROL regulates the dialing rate.

## DEVICE OPERATION

The MK5376 interfaces to two keypad configurations - the 12KEY and 13KEY Modes (see Figures 4 and 5). This flexibility simplifies interfacing to existing keypads and products. The MK5376 can be used in inexpensive telephones with basic $3 \times 4$ matrix keypads to give them repertory dialer features. In 13KEY Mode, the MK5376 allows the keypad to be used for standard signaling and the special repertory functions are only activated by using the "control" (13th) key.
In both modes, keypad entries are decoded, debounced, and (if valid) stored in the LND (Last Number Dialed) buffer that acts much like a FIFO (First-In-First-Out) register. Each subsequent entry is stacked in the buffer. The dialing sequence begins 100 ms after the first digit is accepted. Each digit buffered into the RAM is dialed out with a 98 ms burst of DTMF and a 102 ms intersignal time.

Figure 4 : Keypad Configuration 12Key Mode (tone mode).

| 1 | 2 | 3 |
| :---: | :---: | :---: |
| 4 | 5 | 6 |
| 7 | 8 | 9 |
| $\left\|\begin{array}{c} * \\ \text { STORE } \end{array}\right\|$ | $\stackrel{8}{\text { Lnd }}$ | $\stackrel{\text { \# }}{\text { PaUSE }}$ |

Buffering data into the RAM before signaling is an important feature. This allows less expensive keypads to be used since users cannot enter digits too quickly for the system and the PACIFIER TONE can provide audible feedback after each non-toned key entry. It also guarantees that data stored in the RAM exactly matches the digits actually dialed.
Users can perform consecutive manual and autodialing, if auto-dialing is used to accomplish only a part of the desired number sequence. However, manual and auto-dialing cannot be performed simultaneously.

## NORMAL DIALING

In 12KEY Mode, the "*" (Star) key is the modifier used to control repertory functions. All numeric keys signal normally unless a modifier precedes them. To signal either a "*" or "\#" users must enter these keys twice in succession. The first entry is not signaled or stored.

## LND PRIVACY

D $\quad \mathrm{D}$ ON-HOOK $\square$

A "*", \# input after going on-hook or prior to coming off-hook with erase information stored in the LND buffer.

## AUTO-DIALING (Off-hoof))

The key sequence "*" followed by any digit autodials the number sequence stored in the designated address location. Note auto-dial can take place following manual key inputs.
STORAGE (On-hook)

The number sequence stored in the LND buffer can be transferred to one of the nine other "permanent" locations with the simple sequence "*" followed by the address. New digits may be written into the LND buffer while on-hook. To enter a "*" signal, users enter the "*" key twice in succession as when dialed off-hook.

PABX PAUSE (Off-hook and On-hook)

| D | D | * | \# | N |
| :---: | :---: | :---: | :---: | :---: |

When users input "*" key followed by a "\#", an indefinite pause is stored in a number sequence. Upon redialing the number sequence, the dialer will pause when it encounters "\#". A key input makes it continue.

## KEYPAD CONFIGURATION 12KEY MODE (pulse mode)

Most of the Pulse key operations are identical to those in the 12KEY Tone Mode; PABX Pause is the only exception. In Pulse Mode, the pause is stored with a single "\#" input. Two "\#" inputs store two pauses.
The "*" key exercises the control function ; two "*" inputs are the same as a single input (multiple inputs are not accepted).
Figure 5 : Keypad Sequence 13Key Cofiguration.

## NORMAL DIALING AND LND PRIVACY OPTION (Off-hook)

Normal dialing is straightforward; all keypad entries are stored in the LND (Last Number Dialed) buffer and signaled as each is entered. All digits in the LND register are maintained unless the final key prior to going on-hook is " C ". In the metal mask version, the LND buffer is cleared unless users make a Control entry before going on-hook.
AUTO-DIALING (Off-hook)

## ADDRESS

To auto-dial, users enter the control key "C", followed by the address key, (shown here as " N ", representing memory location $N$ ). As soon as the address key is decoded and debounced, auto-dialing begins. Address zero is used to auto-dial LND.

STORAGE (On-hook)
$D \cdot \mathbf{D} . \quad \mathbf{D} \quad \mathbf{N}$

To store data in a given location (LOC N) users simply enter digits into the LND buffer and copy them to " N " by entering a control key " C " followed by the desired address. Users can copy the last number dialed before going on-hook to another location if they make no entries before the copy operation.

## PABX PAUSE

Users may inject a pause at any point in the dialed sequences by keying in "C" followed by "\#". When this number sequence is redialed, the dialer pauses indefinitely and continues to dial when another key input is received.

ABSOLUTE MAXIMUM RATINGS*

| Parameter | Value | Unit |
| :--- | :---: | :---: |
| DC Supply Voltage | 6.5 | V |
| Operating Temperature | -30 to +60 | ${ }^{\circ} \mathrm{C}$ |
| Storage Temperature | -55 to +85 | ${ }^{\circ} \mathrm{C}$ |

| PSD | Pre-signal Delay | , | 132 |  | ms | 5 |
| ISD | Inter-signal Delay |  | 100 |  | ms | 5 |

Notes : 1. ODBm equals 1 mWatt signal power into a 600 W load or 775 mV .
2. - Single tone (low group) $\mathrm{V}=2.5 \mathrm{~V}$.
3. "Supply voltage $=2.5$ to $6 \mathrm{~V} . \mathrm{R}_{\mathrm{E}}=10 \mathrm{~K} \Omega$.
4. Maximum load which can be connected externally to pin 10 and maintain proper tone levels.
5. These values are directly related to the RC component values connected to Pin 7 , the rate control frequency is nominally 8 kHz .

AC CHARACTERISTICS - PULSE MODE OPERATION

| Symbol | Parameter | Min. | Typ. | Max. | Unit | Notes |
| :---: | :--- | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{P}_{\mathrm{R}}$ | Pulse Rate |  | 10 |  | PPS | 1 |
| PDP | Predigital Pause |  | 172 |  | ms | 1 |
| IDP | Interdigital Pause |  | 940 |  | ms | 1 |
| $\mathrm{~T}_{\text {MO }}$ | Mute Overlap Time |  | 2 |  | ms | 1 |

Note : 1. Typical times assume nominal RC input frequency of 8 kHz . An increase in frequency results in an equal decrease in time values and increase in rate values.

## TONE/PULSE WORLD DIALER WITH LNR

- TWOSELECTPINS ALLOW THE USERTOSELECT 16 DIFFERENT COUNTRY OPTIONS
- SINGLE CHIP MIXED MODE DIALER ALLOWS DIALING IN EITHER TONE OR PULSE MODES. A * OR "SOFTSWITCH" KEY INPUT CAN ALSO BE USED TO SWITCH FROM PULSE TO TONE MODE OPERATION AND IS STORED IN MEMORY
- 28 DIGIT STORAGE WITH LNR (last number redial)
- P.I.N. (personal identify number) PROTECTION METHOD
- SLIDING CURSOR METHOD TO SIMPLIFY PABX DIALING
- HOOKSWITCH DEBOUNCE, TRANSIENTS DUE TO LINE REVERSALS AND DROP-OUTS CAN BE MASKED FOR A PERIOD DETERMINED BY EXTERNAL RC
- POWERED FROM TELEPHONE LINE, LOW STANDBY CURRENT AND OPERATING VOLTAGE
- DTMF SIGNAL CONSISTENT WITH KEY ENTRY PERIOD
- MINIMUM DTMF SIGNAL DURATION/SEPARATION GUARANTEED
- TIMED PABX PAUSE MAY BE STORED IN MEMORY
- TIMED FLASH FOR EXTENDED TIMED BREAK RECALL

## DESCRIPTION

The MK53721 is a 20 pin CMOS mixed mode dialer IC. This dialer provides signalling for both TONE (DTMF) and PULSE (LD) modes of operation. All digits entered are stored in a 28-digit buffer and can be recalled with a single LNR (last number redial) command entry.

The MK53721 can be switched from PULSE to TONE mode operation through the keypad with a */\# key input or softswitch (SS) key input. All key inputs following a softswitch command will generate DTMF signals.

## PIN CONNECTION

KEYPAD CONFIGURATION

| 1 | 2 | 3 | FLASH |
| :---: | :---: | :---: | :---: |
| 4 | 5 | 6 | SS |
| 7 | 8 | 9 | PAUSE |
| $\star$ | 0 | $\#$ | LNR |

## DESCRIPTION (continued)

Two select pins (SELA, SELB) have been provided which allow the part to be customized for various markets. Rather than selecting and modifying individual parameters which would take many pins or mask options each select pin will select groups of options which have been identified for particular markets.

The MK53721 features a Sliding Cursor, AutoPause insertion (on some options), manual Pause, and Flash. The DTMF tone output has a guarenteed minimum duty cycle and extends to match the duration of key inputs.

## ABSOLUTE MAXIMUM RATINGS*

| Parameter | Value | Unit |
| :--- | :---: | :---: |
| DC Supply Voltage | 6.5 | V |
| Operating Temperature | 0 to 60 | ${ }^{\circ} \mathrm{C}$ |
| Storage Temperature | -55 to +125 | ${ }^{\circ} \mathrm{C}$ |
| Maximum Power Dissipation $\left(25^{\circ} \mathrm{C}\right)$ | 500 | mW |
| Maximum Voltage on any Pin | (VDD) $+.3,(\mathrm{VSS})-.3$ | V |

DC ELECTRICAL CHARACTERISTICS( $\mathrm{Ta}=25^{\circ} \mathrm{C}$ unless otherwise specified)

## TIMING DIAGRAMS

Figure 1 : Tone Mode Timing.

Figure 2 : Pulse Mode Timing.

## GENERAL DESCRIPTION

## A-OPTIONS

The SELA pin is used to select groups of parameters and modify the operation of some of the special features. These groups are tailored for specific users. A major benefit of this approach simplifies the design of telephones for the international market. The option groups are selected by connecting the

SELA pin (number 10) to one of the row or column pins for a total of eight possible choices. The Sel-B option pin further defines an additional group of A options by connecting the Sel-B pin to either a column, for options A1-A8, or to a row, for options A9A16. Options can only be changed while "on-hook".

Table 1: A Options.

| OPT | PIN | PPS | M/B | PDP | IDP | FLSH | TONE | Functions |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The default settings for any group, unless specified otherwise in the FUNCTIONS column is :
API = False, DM = False, SS*\# = False, PIN = True, FT = False, Flash Option = F1, D*\#P = False,
Sweden keypad = False, New Zeland = False.

## DEFINTIONS

TONE $x x / y y: x x=$ Tone duration (TDUR), $y y=$ Tone intersignal delay (TISD)
API = autopause insertion (True, False)
DM = data mode, memory bypassed and part xmits tones as simple DTMF generator.
SS*\# = transmit * or \# key on input, even in pulse mode (True, False).
SS*SS = Softswitch sequence [bi-directional] required by Germany (True, False).
PIN = personal id number protection (True, False)
*\#PIN = PIN protection is ignored if * or \# is the first digit (True, False).
FT = flash can only be used in Tone mode (True, False)
F1 = flash option 1, keys following a flash will begin new sequence
F2 = flash option 2, keys following flash will be appended to current sequence and cannot be recalled.
The first group of A-Options are selected by B-options B1 through B4.
A1: OPEN
A2 : UK
A3: FRANCE (PUBLIC)
A4: FRANCE (PRIVATE)
A5 : PANAMA/COLOMBIA (S. AMERICAN COUN-TRIES)
A6 : NEW ZEALAND
A7: SWEDEN/SOME OF NORWAY
A8: USA - 10PPS
The second group of A-Options are selected by B-options B5 through B8.
A9 : HOLLAND/DENMARK
A10: BELGIUM
A11: SPAIN
A12: FRANCE (Data mode)
A13: AUSTRALIA
A14: ISRAEL
A15: ITALY
A16: USA - 20PPS

## B-OPTIONS

SELB pin is used to select a default pulse rate and also determine the fixed delay time used for the

PAUSE command.
There are four alternatives to choose from. Options can be changed only when "on-hook".

Table 2 : B Options.

| Option | Pin | A- OptionsGroup | Pause Duration(sec) |
| :---: | :---: | :---: | :---: |
| B1 | -COL1- | A1-A8 | IDP + 1.1 + IDP |
| B2 | -COL2- |  | IDP + 3.1 + IDP |
| B3 | -COL3- |  | IDP +6.0 + IDP |
| B4 | -COL4- | Indefinite |  |
| B5 | -ROW1- | A9-A16 | IDP + 1.1 + IDP |
| B6 | -ROW2- |  | IDP +3.1+IDP |
| B7 | -ROW3- | IDP +6.0 + IDP |  |
| B8 | -ROW4- | Indefinite |  |

## KEYBOARD INTERFACE

The MK53721 has eight keyboard interface pins which are to connected to a $4 \times 4$ keypad with FORM A (SPST) switches. A 2-of-8 keyboard with negative common may also be used.
The keyboard is disabled while "on-hook". Off-hook, the column and row keys assume opposite logical states. Keyboard scan is enabled when a valid input is detected. The scan frequency is 250 Hz .
On hook, the keypad inputs are disabled eliminating possible current draw in this state. Off hook, the keypad inputs are enabled. A key entry, connecting a single column pin to a single row pin, is detected and the oscillator is activated. The keypad is scanned and debounced to verify the key input and the data is then stored into the LNR buffer (if storable).

## HOOKSWITCH INPUT

The HKS INPUT (HOOKSWITCH) informs the MK53721 of the state of the telephone. A logic "1" (connected to VDD) indicates the telephone set is in the "off-hook" state and dialing is enabled. A logic "0" (connected to VSS) indicates the telephone set is "on-hook", dialing is disabled, and the chip will not draw extra current if keys are depressed. This ensures that only the memory retention current is
required while on hook.
The HKS INPUT is level sensitive which simplifies the implementation of hookswitch debounce. Transients caused by interruptions in loop current during exchange operations will not cause inadvertant "onhook" detection. The length of debounce is determined by the value of a the pullup resistor and capacitor connected externally. The suggested debounce periods range from 50 msec to 500 msec . A valid hookswitch transition will terminate signalling in progress and reset the dialing mode to the default mode determined by the MODE INPUT (pin 2). The HKS debounce time is determined by the following equation:

$$
T(H S D B)=0.75 \times \text { REXT } \times \text { CEXT }
$$

## EARTH LOOP RECALL (ELR OR GND KEY)

Earth loop recall is not generated by the MK53721 but can be detected by applying a logic " 0 " level directly to the hookswitch. The hookswitch debounce is bypassed by applying logic levels directly to the HKS pin (input not connected through external resistor). The ELR or GND KEY detect is identical to a hookswitch input without the debounce. Any digits dialed after ELR or GND key will reset the memory and be treated as a new number in the LNR buffer.

## LAST NUMBER REDIAL

LNR (last number redial) command causes the contents of the LNR buffer to be dialed. Numbers which include a softswitch are limited by P.I.N. protection described below. LNR does not have to be the initial key input since the MK53721 features a "sliding cursor" dialing method.
The LNR buffer can store 28 digits but any number of digits may be dialed manually. The memory storage will wrap-around after the first 28 digits have been entered and the additional inputs will be stored beginning in the first memory location. After wrap-around has occured the LNR command will be disabled to prevent misdials.

## FLASH

The FLASH command is stored in the LNR buffer and when signaled it initiates a timed break. This ti-
ming is determined by the options selected. Flash option F1 will reset the memory after a flash and additional inputs will begin a new number sequence. If this option is selected new digits will not be accepted until the FLASH is completed.

Flash option F2 will continue accepting inputs and storing these sequentially in the buffer. These digits cannot be redialed.

In both cases, signalling will revert to the default dialing mode determined by the MODE INPUT following the FLASH command execution and the FLASH itself is never redialed.

Mask out during Flash $=$ Tpdp + Flash duration + Tidp.

Table 3 : Flash Key Options.

## SLIDING CURSOR

The sliding cursor feature simplifies PABX access and redial. The MK53721 will compare all digits as they are entered to the previous memory contents.

If all digits entered equal the memory contents the LNR command can be activated at any point in the dialing sequence and the remaining data will be redialed. LNR is inhibited if there is a digit mismatch.

Table 4 : Sliding Cursor Operation.

| Mode | Key Input | Output | Description |
| :---: | :---: | :---: | :--- |
| T/P | 123345 | 1223 | 4 |
| T/P | LND | 2 | Normal Dial |
| T/P | 123 LND | 1223445 | Redial |
| T/P | 124 LND | 1224 | Sliding Cursor |
| T/P | 12 | 12 | Sliding Cursor, Invalid |
| T/P | LNR | Normal Dial |  |

## SOFTSWITCH, P.I.N. PROTECTION

Softswitch feature allows the dialing mode of the dialer to be switched from Pulse Mode to Tone Mode operation with a key input. Two methods are available to accomplish this, first is the SS key and second is the * or \# key while in Pulse mode.
The P.I.N. (PERSONAL IDENTIFY PROTECTION) feature of the MK53721 will protect numbers which
are likely to be used in confidential transactions. Digits entered after a * or \# key in TONE mode, or "softswitch" command (either a * input or SS input while in PULSE mode) are considered private. These digits cannot be redialed and therefore the users privacy is not compromised. The exception to this is a * or \# key at the beginning of a sequence, in this case redial of the entire sequence is allowed.

Table 5 : Softswitch Operation.

| Mode | Key Input | Output | Description |
| :---: | :---: | :---: | :---: |
| PULSE | 123 * 45 | 123 <TDMF> 45 | Softswitch, SS $\star$ \# = False |
| PULSE | $123 \star 45$ | $123<$ TDMF>* 45 | Softswitch, SS $\star$ \# = True |

| TONE | $\star 123 \star 45$ | $\star 123 \star 45$ | If firest key is $\star$ or \#, then $\star$, \# is redialed |
| TONE | LNR | $\star 123 \star 45$ | SS* \# = True |
| TONE | LNR | $\star 123$ | SS* \# = False |

## PAUSE

The PAUSE command is used to insert a fixed time delay into a number sequence. The dialer will delay a fixed time when redialing the number. The delay is programmable with the SELB option pin. If an indeterminate delay is selected the dialer will stop during redial at the point where the PAUSE function was entered. Auto-dialing is resumed by entering the PAUSE key.
An AUTO-PAUSE INSERTION (API) feature is also available as an option. The pause is inserted auto-
matically into a number sequence if manual dialing is interrupted by a delay of more than one second following the signaling of the last digit entered if in tone mode operation. In Pulse mode operation, the delay will be inserted automatically if a manual digit has not been entered within an IDP time following the completion of the previous digit. Not more than two APIs' will be entered for each number sequence.

Table 6 : Pause Operation.

| Mode | Key Input | Output | Description |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & \text { T/P } \\ & \text { T/P } \end{aligned}$ | $\begin{array}{ll} 123 \ldots 45 \\ \text { LNR } & \\ \hline \end{array}$ | $\begin{array}{lllll} 1 & 2 & 3 & 4 & 5 \\ 1 & 2 & 3 & \ldots \end{array}$ | Manual Dial with Delay <br> Redial, Pause Inserted if Autopause <br> = True |

## DATA MODE

The DATA MODE feature allows the MK53721 to be put into a mode where it operates just like a simple tone dialer, for entering long sequences of tones to a remote service without disturbing the LNR buf-
fer. If the DM option is selected, all digits entered after a * or \# key will be toned out with no minimum tone duration, and will not clear the LNR buffer regardless of how many digits are output.

Table 7 : Data Mode Option.

| Mode | Key Input | Output | Description |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & \hline T \\ & T \\ & T \end{aligned}$ | $123 \star 45 \ldots \mathrm{~N}$ <br> LNR <br> $\star 123 \star 45 \ldots N$ <br> LNR | $\begin{array}{lllll} 1 & 2 & 3 \\ 1 & \star & 4 & 5 & \ldots \\ & N \\ \star & 1 & 2 & 3 & \\ & 4 & 5 & & \\ \end{array}$ | Data Mode (DM) Active After $\star$ or \# Digits before DM are redialed. | $\begin{aligned} & \hline P \\ & P \\ & P \end{aligned}$ | $\begin{aligned} & 123 \star 45 \ldots \mathrm{~N} \\ & 123 \star 45 \ldots \mathrm{~N} \\ & \text { LNR } \end{aligned}$ |  | Softswitch to DM on $\star$ or \#, SS $\star$.\# = True <br> Softswitch to DM, SS 太 \# = False Digits before DM are redialed. |
| $\begin{aligned} & \hline \mathrm{P} \\ & \mathrm{P} \\ & \mathrm{P} \\ & \mathrm{P} \end{aligned}$ | $\star 123 \star 45 \ldots \mathrm{~N}$ LNR $\star 123 \star 45 \ldots N$ <br> LNR |  | SS $\star$ \# = False SS $\star$ \# = False, softswitches but nothing redialed. <br> SS $\star$ \# = True <br> SS * \# = True |

## DTMF OPERATION

The DTMF OUTPUT is driven by a bipolar (NPN) emitter follower with the collector tied to VDD. The DTMF OUT signal is a summation of the keyboard selected High group (column) and Low group (row) tones. The amplitude of these tones is determined internal to the chip and is independent of supply.
The tones are synthesized using a resistor tree with
sinusoidally weighted taps. The frequency and accuracy of the synthesized tones is listed in the table 8 . Note, variations in the oscillator frequency (using the 3.579545 MHz crystal) will be reflected in the frequency of the synthesized tones.
Single tone may be generated when using options A8 or A16, by symultaneously pressing two buttons in the same row or column.

Table 8 : DTMF Output Frequencies.

| Key Input | StandardFrequency | ActualFrequency | \% Deviationfrom <br> Standard |
| :---: | :---: | :---: | :---: |
| -ROW1- | 697 | 699.1 | +0.31 |
| -ROW2- | 770 | 766.2 | -0.49 |
| -ROW3- | 852 | 847.4 | -0.54 |
| -ROW4- | 941 | 948.0 | +0.74 |
| -COL1- | 1209 | 1215.9 | +0.57 |
| -COL2- | 1336 | 1331.7 | -0.32 |
| -COL3- | 1477 | 1471.9 | -0.35 |

## PULSE OPERATION

In Pulse operation the MK53721 converts keypad inputs into a series of pulses to simulate a rotary dialer. The Pulse Output becomes active following the debounce period and a short predigital pause period. A Mask Output is provided to remove the speech network form the line or to attenuate the current spikes which reach the receiver when Pulse dialing. The Mask output goes active a predigital pause
prior to the first break and remains active until an IDP period following the output of the last digit from the buffer. The nominal pulse output rate is 10pps although this is selectable by the Select Option pins.
In pulse mode operation the number of pulses associated with each key can be modified to meet standards of nations such as Sweden, some of Norway, and New Zealand. These options are available through the SELA and SELB input pins.

Table 9 : Pulse Output Options.

|  | Normal |  | Sweden |  | New Zealand |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $0 \ldots$ | 10 Pulses | $0 \ldots$ | 1 Pulse | $0 \ldots$ | 10 Pulses |

## TYPICAL APPLICATIONS

The MK53721 is a single chip Tone Pulse World Dialer with 28 -digit last number redial, which provides the necessary signals for DTMF (tone) or loop disconnect (pulse) dialing. The typical application circuit shown in figure 3 illustrates one way the MK53721 Tone Pulse dialer can be used with an integrated speech circuit to produce a multi-standard telephone. The circuit is connected to the telephone line through a polarity guard integrated circuit that assures proper voltage polarity to the circuit, regardless of telephone line polarity, as well as limiting the voltage at the polarized side. The 2 -to- 4 wire conversion, muting of the transmitter and receiver, and provision of regulated supply voltage to the MK53721 is accomplished using an SGS-THOMSON L3280 integrated speech circuit. The L3280 also takes the MK53721 DTMF output and modulates the line with that signal. Because of the various World Dialer timing options selectable with the MK53721, the application can be easily adapted to meet the standards of almost any country.

In this circuit, Pulse dialing (which consists of a series of momentary interruptions of loop current) is achieved by the Pulse output of the MK53721 controlling transistor Q1, Q2 and Q5 to break and make the loop current through the speech network. The MK53721 MASK output provides the logic level to
the L3280 MUTE input to cause muting of the loud pops which would otherwise be heard at the receiver due to the pulsing of the loop current through the speech network.

Tone signalling requires that the loop current be modulated with the appropriate DTMF signal. The DTMF output of the MK53721 is coupled to the DTMF driver circuitry of the L3280 via a filter network comprised of C8, C9, R12, R13 and Q3. The jumper J1 allows the user to select whether or not to use the filter network required to meet some country specifications. The MK53721 MUTE output provides the logic level to the L3280 MUTE input to mute the transmitter and reduce to an acceptable level the tone heard at the receiver.
The mode of operation (Tone or Pulse) is controlled by switch S1. In Pulse Mode, the Softswitch key (SS or * key) can be used to change from Pulse to Tone Mode. Going on-hook and back off-hook will cause the MK53721 to revert to the mode selected by the S1, but the Softswitch function can be redialed. The signalling mode may be changed at any time, so as to allow mixed Pulse and Tone dialing.
The current required for long term memory retention with the MK53721 is typically 0.3 uA . A battery is therefore not required if a resistor is used to provide the small amount of memory retention from the line when on-hook.

Figure 3 : MK53721 Typical Application.

## SINGLE NUMBER PULSE TONE SWITCHABLE DIALER

- SINGLE CHIP DTMF AND PULSE DIALER
- SOFTSWITCH CHANGES SIGNALING MODE FROM PULSE TO TONE
- RECALL OF LAST NUMBER DIALED (up to 28 digits long)
- FLASH KEY INPUT INITIATES TIMED HOOK FLASH
- TIMED PABX PAUSE
- 8 TONES PER SECOND DIALING IN TONE MODE AND 10 PPS IN PULSE MODE
- DTMF ACTIVE UNTIL KEY RELEASE
- MINIMUM DTMF DURATION/SEPARATION GUARANTEED ( $74 / 54 \mathrm{~ms}$ )
- PACIFIER TONE PROVIDES AUDIBLE INDICATION OF VALID KEY INPUT FOR NONDTMF KEY ENTRIES
- POWERED FROM TELEPHONE LINE, LOW OPERATING VOLTAGE FOR LONG LOOP APPLICATIONS

## DESCRIPTION

The MK53731 is a Silicon Gate CMOS IC that provides necessary signals for either DTMF or loop disconnect (pulse) dialing. The MK53731 buffers up to 28 digits into memory that can be later redialed with a single key input. This memory capacity is sufficient for local, long distánce, overseas, and even computerized long-haul networks. Users can store all 12 signaling keys and access several unique functions with single key entries. These functions include : Last Number Dialed (LND), Softswitch, Flash, and Pause. Figure 2 shows the keypad configuration.
A LND key input automatically redials the last number dialed.

Two features simplify PABX dialing. The pause key stores a timed pause in the number sequence. Redial is then delayed until an outside line can be accessed or some other activity occurs before normal signalling resumes. The FLASH key simulates a 560 ms hook flash to transfer calls or to activate other special features provided by the PABX or a central office.

Figure 1 : Pin Connection (top view).

Figure 2 : Keypad Configuration.

## FUNCTIONAL PIN DESCRIPTION

V+
Pin 1. $\mathrm{V}_{+}$is the positive supply for the circuit and must meet the maximum and minimum voltage requirements. (see Electrical Specifications).

## MODE

Input. Pin 2. MODE determines the dialer's default operating mode. When the device is powered up or the hookswitch input is switched from on-hook, $(\mathrm{V}+)$, to off-hook, ( $\mathrm{V}-$ ), the default determines the signaling mode. A V+ connection defaults to tone mode operation and a V - connection defaults to pulse mode operation.
When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the * key, or softswitch, is depressed. Subsequent * key inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to offhook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.

## $\overline{\mathrm{C} 1}, \overline{\mathrm{C} 2}, \overline{\mathrm{C} 3}, \overline{\mathrm{C} 4}, \overline{\mathrm{R} 4}, \overline{\mathrm{R} 3}, \overline{\mathrm{R} 2}, \overline{\mathrm{R} 1}$

Keyboard inputs. The MK53731 interfaces with either the standard $2-\mathrm{of}-8$ with riegative common or the single-contact (Form A) keyboard.
A valid keypad entry is either a single Row connected to a single Column or V-simultaneously presented to both a single Row and Column. In its quiescent or standby state, during normal off-hook operation, either the Rows or the Columns are at a logic level $1(\mathrm{~V}+)$. Pulling one input low enables the on-chip oscillator. Keyboard scanning then begins. Scanning consists of Rows and Columns alternately switching high through on-chip pullups. After both a Row and Column key have been detected, the debounce counter is enabled and any noise (bouncing contacts, etc.) is ignored for a debounce period (TKD) of 32 ms . At this time, the keyboard is sampled and if both Row and Column information are valid, the information is buffered into the LND location. If switched on-hook (pin 17 to pin 1), the keyboard inputs are pull high through on-chip pull-up resistors.
In the tone mode, if 2 or more keys in the same row or if 2 or more keys in the same column are depressed a single tone will be output. The tone will correspond to the row or column for which the 2 keys were pushed. This feature is for test purposes, and single tones will not be redialed.
Also in the tone mode, the output tone is continuous in manual dialing as long as the key is pushed. The output tone duration follows the table 1.

Table 1. Output Tone Duration.

| Key - Push Time, $\mathrm{T}^{*}$ | Tone Output ${ }^{*}$ |
| :--- | :--- |
| $\mathrm{~T} \leq 32 \mathrm{~ms}$ | No Output. Ignored by <br> MK53731. |
| $32 \mathrm{~ms} \leq \mathrm{T} \leq 75 \mathrm{~ms}$ <br> $+\mathrm{T}_{\mathrm{DK}}$ | 75 ms Duration Output. |
| $\mathrm{T} \geq 75 \mathrm{~ms}+\mathrm{T}_{\mathrm{KD}}$ | Output Duration $=$ <br> $\mathrm{T}-\mathrm{T}_{\mathrm{KD}}$ |

* Note : $\mathrm{T}_{\mathrm{KD}}$ is the keypad debounce time which is typically 32 ms .

When redialing in the tone mode, each DTMF output is 75 ms duration, and the tone separation (intersignal delay) is 50 ms .

V-
Input. Pin 6 is the negative supply input to the device. This is the voltage reference for all specifications.

## OSC1, OSC2

Pin 7 (input), pin 8 (output). OSC1 and OSC2 are connections to an on-chip inverter used as the timing reference for the circuit. It has sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation from this standard is directly reflected in the Tone output frequencies. The crystal oscillator provides the time reference for all circuit functions. A ceramic resonator with tolerance of $\pm 0.25$ \% may also be used.

## DTMF OUTPUT

Output. Pin 10. An NPN transistor emitter with a collector tied to $\mathrm{V}+$ drives the DTMF OUTPUT pin. The transistor base is connected to an on-chip operational amplifier that mixes the Row and Column tones. Figure 7 shows the timing at this pin.
The DTMF OUTPUT is the summation of a single Row frequency and a single Column frequency. A typical single tone sine wave is shown in Figure 4. This waveform is synthesized using a resistor tree with sinusoidally weighted taps.

The MK53731 is designed to operate from an unregulated supply ; the TONE LEVEL is supply independent, and the single row tone output level will be typically :

$$
\mathrm{T}_{01}=-12 \mathrm{dBm} \pm 1 \mathrm{~dB}
$$

The DC component of the DTMF output while active is described by the following equation :

$$
V_{D C 1}=0.3 V_{+}+0.5 \text { Volts }
$$

Figure 4 : Typical Single Tone.

Figure 5 : Typical Dual Tone.

Figure 6 : Typical Spectral Response.

## PACIFIER TONE

Output. Pin 11. A 500 Hz square wave is activated upon acceptance of a valid key input, after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. In pulse mode, all valid key entries activate the pacifier tone. In tone mode, any nonDTMF (FLASH, PAUSE, LND, SOFTSWITCH) entry activates the pacifier tone. The pacifier tone provides audible feedback, confirming that the key has been properly entered and accepted.

## MUTE OUTPUT

Output. Pin 12. This pin is the MUTE OUTPUT for both tone and pulse modes. Timing is dependent upon mode.
The MUTE OUTPUT consists of an open drain Nchannel device. During standby, the output is high impedance and generally has an external pullup resistor to the positive supply.
In the tone mode, MUTE OUTPUT is used to remove the transmitter and the receiver from the network during DTMF signaling. During dialing, MUTE OUTPUT is active continuously until dialing is completed. MUTE OUTPUT goes active when any key is pushed.
In the pulse mode, MUTE OUTPUT is used to remove the receiver and the network from the line. Different circuitry is required for tone and pulse muting external to the IC and applications using both modes would not necessarily share circuitry. MUTE OUTPUT timing is shown in Figure 8 for pulse mode signaling and Figure 7 for tone mode signaling. MUTE OUTPUT is active during each digit, and not active during the interdigit time. In both tone and pulse modes, MUTE OUTPUT goes active 40 ms before PULSE OUTPUT for a FLASH.

## HKS

Input. Pin 17. Pin 17 is the hookswitch input to the MK53731. This is a high-impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input causes the on-chip logic to initialize, terminating any operation in progress at the time. The signaling mode defaults to the mode selected at pin 2 . Figure 8 illustrates the timing for this pin.

## PULSE OUTPUT

Output. Pin 18. This is an output consisting of an open drain N -channel device. In either pulse or tone mode, the FLASH key will cause a 560 ms output pulse at pin 18.

## DEVICE OPERATION (Tone Mode)

When the MK53731 is not actively dialing, it consumes very little current. While on-hook, all keypad input pins are internally pulled high. Row and Column inputs assume opposite states off-hook. The circuit verifies that a valid key has been entered by alternately scanning the Row and Column inputs. If the input is still valid following 32 ms of debounce, the digit is stored into memory, and dialing begins after a pre-signal delay of approximately

40 ms (measured from initial key closure). Output tone duration is shown in Table 1.
The MK53731 allows manual dialing of an indefinite number of digits, but if more than 28 digits are dialed, the 53731 will "wrap around". That is, the extra digits beyond 28 will be stored at the beginning of the LND buffer, and the first 28 digits will no longer be available for redial.

Table 2 : DTMF Output Frequency.

| Key Input | Standard Frequency | Actual Frequency | \% Deviation |
| :---: | :---: | :---: | :---: |
| ROW 1 | 697 | 699.1 | +0.31 |
| 2 | 770 | 766.2 | -0.49 |
| 3 | 852 | 847.4 | -0.54 |
| 4 | 941 | 948.0 | +0.74 |
| COL 1 | 1209 | 1215.9 | +0.57 |
| 2 | 1336 | 1331.7 | -0.32 |
| 3 | 1477 | 1471.9 | -0.35 |

Figure 7 : Tone Mode Timing.

Note : For this example, key entries are $\leq 75 \mathrm{~ms}$, but $\geq 32 \mathrm{~ms}$.

Figure 8 : Pulse Mode Timing.

NORMAL DIALING (off-hook)

...ETC

Normal dialing is straightforward, all keyboard entries will be stored in the buffer and signaled in succession.

LAST NUMBER DIALED (LND)

Last number dialing is accomplished by entering the LND key.

## PAUSE

D PAUSE $\quad$ D $\quad$...ETC

A pause may be entered into the dialed sequence at any point by keying in the special function key, PAUSE. Pause inserts a 1.1-second delay into the dialing sequence. The total delay, including pre-digital and post-digital pauses is shown in Table 3.

## HOOK FLASH

...ETC

Hook flash may be entered into the dialed sequence at any point by keying in the function key, FLASH. Flash consists of a timed Break of 560 ms . The FLASH function is stored in memory, but it will not be redialed as such. When a FLASH key is pressed, no further key inputs will be accepted until the hookflash function ( 560 ms break) has been dialed. The key input following a FLASH will be stored as the initial digit of a new number (overwriting the number dialed prior to the FLASH) unless it is another FLASH. Consecutive FLASH entries after a number is dialed will be stored sequentially in the LND memory and a subsequent LND entry will cause the redial of that number with a delay, but not hookflash breaks, at the end of the redialing sequence. When redialing in tone mode, MUTE OUTPUT will remain active during the flash delay period.

## SOFTSWITCH

When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever
the * key, or SOFTSWITCH, is depressed. Subsequent * key inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from
pulse to tone. After returning to on-hook and back to off-hook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.

Table 3 : Spécial Function Delays.
Each delay shown below represents the time required from after the special function key is depressed until a new digit can be dialed.
The time is considered "FIRST" key is all previous inputs have been completed dialed. The time is considered "AUTO" if in redial, or if previous dialing is still in progress.

| Function | First/Auto | Delay (seconds) |  |
| :--- | :--- | :---: | :---: |
|  |  | Pulse | Tone |
| SOFTSWITCH | FIRST | 1.15 |  |
|  | AUTO | 1.85 | 1.15 |
| PAUSE | FIRST | 1.84 | 1.20 |

## DIALER WITH FOUR EMERGENCY NUMBERS

- SINGLE CHIP DTMF AND PULSE DIALER
- STORES 5 18-DIGIT TELEPHONE NUMBERS, INCLUDING LAST NUMBER DIALED
- SOFTSWITCH CHANGES SIGNALING MODE FROM PULSE TO TONE
- SINGLE BUTTON REDIAL OF ALL 5 MEMORIES
- FLASH KEY INPUT INITIATES TIMED HOOK FLASH
- 8 TONES PER SECOND DIALING IN TONE MODE AND 10 PPS IN PULSE MODE
- DTMF ACTIVE UNTIL KEY RELEASE
- MINIMUM DTMF DURATION/SEPARATION GUARANTEED (74/54ms)
- PACIFIER TONE PROVIDES AUDIBLE INDICATION OF A VALID KEY INPUT FOR NONDTMF KEY ENTRIES
- POWERED FROM TELEPHONE LINE, LOW OPERATING VOLTAGE FOR LONG LOOP APPLICATIONS

## DESCRIPTION

The MK53760 is a Silicon Gate CMOS IC that provides necessary signals for either DTMF or loop disconnect (pulse) dialing. The MK53760 buffers up to 18 digits into memory that can be later redialed with a single key input. Up to 4 repertory numbers may be stored. Users can store all 12 signaling keys and access several unique functions with single key entries. These functions include : Last Number Dialed (LND), Softswitch, Flash, and 4 memories. Figure 2 shows the keypad configuration.
A LND key input automatically redials the last number dialed, and the MEM keys provide single key access to all memory locations for auto-dialing.
The FLASH key simulates' a 560 ms hook flash to transfer calls or to activate other special features provided by the PABX or a central office.
The PAUSE key allows the user to insert a delay in dialing for functions such as the pause in accessing an outside line when reading from a PABX.
The PROG key provides an easy way to program a number into any memory location (MEM1 - MEM4) whether on-hook or off-hook.

Figure 1 : Pin Connection.

Figure 2 : Keypad Configuration.

## FUNCTIONAL PIN DESCRIPTION

## V+

Pin 1. V+ is the positive supply for the circuit and must meet the maximum and minimum voltage requirements (see Electrical Specifications).

## MODE

Input. Pin 2. MODE determines the dialer's default operating mode. When the device is powered up or the hookswitch input is switched from on-hook, ( $\mathrm{V}_{+}$), to off-hook, (V-), the default determines the signaling mode. A V+connection defaults to tone mode operation and a V- connection defaults to pulse mode operation.
When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the *key, or softswitch, is depressed. Subsequent *key inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to offhook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.
$\overline{\mathrm{C} 1}, \overline{\mathrm{C} 2}, \overline{\mathrm{C} 3}, \overline{\mathrm{C} 4}, \overline{\mathrm{R} 5}, \overline{\mathrm{R} 4}, \overline{\mathrm{R} 3}, \overline{\mathrm{R} 2}, \overline{\mathrm{R} 1}$
Keyboard inputs. The MK53760 interfaces with either the standard 2-of-9 with negative common or the single-contact (Form A) keyboard.
A valid keypad and entry is either a single Row connected to a single Column or V- simultaneously presented to both a single Row and Column. In its quiescent or standby state, during normal off-hook operation, either the Rows or the Columns are at a logic level $1(\mathrm{~V}+)$. Pulling one input low enables the on-chip oscillator. Keyboard scanning then begins. Scanning consists of Rows and Columns alternatively switching high through on-chip pullups. After both a Row and Column key have been detected, the debounce counter is enabled and any noise (bouncing contacts, etc.) is ignored for a debounce period (TKD) of 32ms. At this time, the keyboard is sampled and if both Row and Column information are valid, the information is buffered into the LND location. If switched on-hook (pin 19 to pin 1), the keyboard inputs all pull high through on-chip pullup resistors.
In the tone mode, if 2 or more keys in the same row or column are depressed a single tone will be output. The tone will correspond to the row or column for which the 2 keys were pushed. This feature is for test purposes.
Single tones will not be redialed.
Also in the tone mode, the output tone is continuous in manual dialing as long as the key is pushed. The output tone duration follows the table below :

Table 1 : Output Tone Duration.

| Key-Push Time, $\mathbf{T}^{*}$ | Tone Output ${ }^{*}$ |
| :--- | :--- |
| $T \leq 32 \mathrm{~ms}$ | No Output Ignored by <br> MK53760. |
| $32 \mathrm{~ms} \leq \mathrm{T} \leq .75 \mathrm{~ms}+\mathrm{T}_{K D}$ | 75 ms Duration Output. |
| $\mathrm{T} \geq 75 \mathrm{~ms}+\mathrm{T}_{\text {KD }}$ | Output Duration = <br> $\mathrm{T}-\mathrm{T}_{K D}$ |

*Note : $T_{K D}$ is the key pad debounce time which is typically 32 ms .
When redialing in the tone mode, each DTMF output is 75 ms duration, and the tone separation (intersignal delay) is 50 ns .

V-
Input. Pin 7 is the negative supply input to the device. This is the voltage reference for all specifications.

OSC1, OSC2
Pin 8 (input), pin 9 (output). OSC1 and OSC2 are connections to an on-chip inverter used as the timing reference for the circuit. It has have sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation from this standard is directly reflected in the Tone output frequencies. The crystal oscillator provides the time reference for all circuit functions. A ceramic resonator with tolerance of $\pm 0.25 \%$ may also be used.

## DTMF OUTPUT

Output. Pin 11. An NPN transistor emitter with a collector tied to $\mathrm{V}_{+}$drives the DTMF OUTPUT pin. The transistor base is connected to an on-chip operational amplifier that mixes the Row and Column tones. Figure 7 shows the timing at this pin.

The DTMF OUTPUT is the summation of a single Row frequency and a single Column frequency and a single Column frequency. A typical single tone sine wave is shown in figure 4. This waveform is synthesized using a resistor tree with sinusoidally weighted taps.
The MK53760 is designed to operate from an unregulated supply : the TONE LEVEL is supply independent, and the single row tone output level will be typically :

$$
\mathrm{T}_{\mathrm{oi}}=-12 \mathrm{dBm} \pm 1 \mathrm{~dB}
$$

The DC component of the DTMF output while active is described by the following equation :

$$
\mathrm{VDC}_{1}=0.3 \mathrm{~V}++0.5 \text { Volts }
$$

Figure 3 : MK53760 Functional Block Diagram.

Figure 4 : Typical Single Tone.

Figure 5 : Typical Dual Tone.

## PACIFIER TONE OUTPUT/CHIP DISABLE INPUT

Pin 12. PAC tone is an output. The pacifier tone provides audible feedback, confirming that the key has been properly entered and accepted. A 500 Hz square wave is activated upon acceptance of a valid key input, after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. In pulse mode, all key entries activate the pacifier tone. In tone mode, any non-DTMF key (LND, FLASH, MEM, PROG) entry activates the-pacifier tone. When programming the chip, all valid key entries activate the pacifier tone in either pullse or tone mode. The CHIP DISABLE is an input. When pin 12 is switched low, through a resistor ( 10 K to 100 K ), the MK53760 is enabled. When pin 12 is switched to $\mathrm{V}_{+}$ through the resistor, all keypad inputs are pulled high, and the MK53760 will ignore all keypad inputs. When the chip is disabled, it will not dial, and it can-
not be programmed. The chip will only be disabled when the circuit is inactive (not dialing) and Pin 12 is switched high.

Figure 6 : Typical Spectral Response.

Figure 7 : Tone Mode Timing.

Notes : 1. For this example, key entries are $\leq 75 \mathrm{~ms}$, but $\geq 32 \mathrm{~ms}$.
2.- MUTE goes active after any key is depressed.

Figure 8 : Pulse Mode Timing.

Table 2 : DTMF Output Frequency.

| Key Input |  | Standard Frequency | Actual Frequency | \% Deviation |
| :---: | :---: | :---: | :---: | :---: |
| ROW | 1 | 697 | 699.1 | +0.31 |
|  | 2 | 770 | 766.2 | -0.49 |
|  | 3 | 852 | 847.4 | -0.54 |
|  | 4 | 941 | 948.0 | +0.74 |
| COL | 1 | 1209 | 1215.9 | +0.57 |
|  | 2 | 1477 | 1331.7 | -0.32 |
|  | 3 | 1471.9 | -0.35 |  |

## MUTE OUTPUT

Output. Pin 13. This pin is the MUTE OUTPUT for both tone and pulse modes. Timing is dependent upon mode.
The MUTE OUTPUT consists of an open drain N channel device. During standby, the output is high impedance and generally has an external pullup resistor to the positive supply.
In the tone mode, MUTE OUTPUT is used to remove the transmitter and the receiver from the network during DTMF signaling. During dialing, MUTE OUTPUT is active continuously until dialing is completed. MUTE OUTPUT goes active when any key is pushed.
In the pulse mode, MUTE OUTPUT is used to remove the receiver and the network from the line. Different circuitry is required for tone and pulse muting external to the IC and applications using both modes
would not necessarily share circuitry. MUTE OUTPUT timing is shown in figure 8 for pulse mode signaling and figure 7 for tone mode signaling. MUTE OUTPUT is active during each digit, and not active during the interdigit time. In both tone and pulse modes, MUTE OUTPUT goes active 40 ms before PULSE OUTPUT for a FLASH.

## HKS

Input Pin 19. Pin 19 is the hookswitch input to the MK53760. This is a high-impedance input and must be switched high for on-hook operation or low for ofhook operation. A transition on this input causes the on-chip logic to initialize, terminating any operation in progress at the time. The signaling mode defaults to the mode selected at pin 2 . Figure 8 illustrates the timing for this pin.

## PULSE OUTPUT

Output. Pin 20. This is an output consisting of an open drain N -channel device. In either pulse or tone mode, the FLASH key will cause a 560 ms output pulse at pin 20.

## dEVICE OPERATION

When the MK53760 is not actively dialing, it consumes very little current. Row and Column inputs assume opposite states off-hook. The circuit verifies that a valid key has been entered by alternately scanning the Row and Column inputs. If the input is still valid following 32 ms of debounce, the digit is stored into memory, and dialing begins after a pre-signal delay of approximately 40 ms (measured from initial key closure). Output tone duration is shown in table 1.
The MK53760 allows manual dialing of an indefinite number or digits, but if more than 18 digits are dialed per number, the MK53760 "wrap around". That is, the extra digits beyond 18 will be stored at the beginning of the LND buffer, and the first 18 digits will no longer be available for redial. During autodial from LND or any MEM location, key inputs are not accepted, but they will suspend dialing until released.

NORMAL DIALING (off-hook)

...ETC

Normal dialing is straightforward, all keyboard entries will be stored in the buffer and signaled in succession.

LAST NUMBER DIALED (LND)

Last number dialing is accomplished by entering the LND key.

## SOFTSWITCH

When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the * key is depressed. Subsequent * inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to off-hook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.

HOOK FLASH

...ETC

Hook flash may be entered into the dialed sequence at any point by keying in the function key, FLASH. Flash consists of a timed Break of 560 ms . The FLASH function is stored in memory, but it will not be redialed as such. When a FLASH key is pressed, no further key inputs will be accepted until the hookflash function ( 560 ms break) has been dialed. The key input following a FLASH will be stored as the initial digit of a new number (overwriting the number dialed prior to the FLASH) unless it is another FLASH. Consecutive FLASH entries after a number is dialed will be stored sequentially in the LND memory and a subsequent LND entry will cause the redial of that number with a delay, but not hookflash breaks, at the end of the redialing sequence. When redialing in tone mode, MUTE OUTPUT will remain active during the flash delay period.
PAUSE

D
...ETC
A Pause may be entered into the dialed sequence at any point by keying in the special function key, PAUSE. Pause inserts a 1.1-second delay into the dialing sequence. The total delay, including pre-digital and post-digital pauses is shown in table 3.

## PROGRAMMING AND REPERTORY DIALING

## PROGRAMMING AND REPERTORY DIALING

Programming is independent of HKS (pin 19) and MODE (pin 2).
To program, enter the following :
PROG, Digit 1, Digit 2, ..., MEM (Location 1-4). When programming, dialing is inhibited.
To dial a number from repertory memory (HKS must be low) enter the single key:

MEM (location 1-4)
To save the last number dialed : PROG, MEM (location 1-4)

Table 3 : Special Function Delays.
Each delay shown below represents the time required from after the special function key is depressed until a new digit can be dialed.
The time is considered "FIRST" key is all previous inputs have been completed dialed. The time is considered "AUTO" if in redial, or if previous dialing is still in progress.

| Function | First/Auto |  | Delay (seconds) |  |
| :--- | :--- | :---: | :---: | :---: |
|  |  | Pulse | Tone |  |
| SOFTSWITCH | FIRST | 0.40 |  |  |
|  | AUTO | 1.10 | 1.15 |  |
| PAUSE | FIRST | 1.84 | 1.20 |  |

SGS-THOMSON

## REPERTORY DIALER

- SINGLE CHIP DTMF AND PULSE DIALER
- SOFTSWITCH CHANGES SIGNALING MODE FROM PULSE TO TONE
- NINE NUMBER REPERTORY PLUS RECALL OF LAST NUMBER DIALED (18 digits each)
- FLASH KEY INPUT INITIATES TIMED HOOK FLASH
- 8 TONE PER SECOND DIALING IN TONE MODE AND 10 PPS IN PULSE MODE
- DTMF ACTIVE UNTIL KEY RELEASE
- MINIMUM DTMF DURATION/SEPARATION GUARANTEED (74/54 ms)
- PACIFIER TONE PROVIDES AUDIBLE INDICATION OF VALID KEY INPUT FOR NONDTMF KEY ENTRIES
- POWERED FROM TELEPHONE LINE, LOW OPERATING VOLTAGE FOR LONG LOOP APPLICATIONS

## DESCRIPTION

The MK53761 is a Silicon Gate CMOS IC that provides necessary signals for either DTMF or loop disconnect (pulse) dialing. The MK53761 buffers up to 18 digits into memory that can be later redialed with a single key input. Up to nine repertory numbers may be stored. Users can store all 12 signaling keys and access several unique functions with single key entries. These functions include : Last Number Dialed (LND), Softswitch, and Flash. Figure 2 shows the keypad configuration.
A LND key input automatically redials the last number dialed. The PROG key provides an easy way to program a number into any memory location (1-9) whether on-hook on off-hook. The MEMkey allows easy redialing of the number stored in memory locations (1-9).
The FLASH key simulates a 560 ms hook flash to transfer calls or to activate other special features provided by the PABX or a central office.

Figure 1 : Pin Connection.

Figure 2 : Keypad Configuration.

M88MK53761-81A

## FUNCTIONAL PIN DESCRIPTION

V+
Pin 1. $\mathrm{V}_{+}$is the positive supply for the circuit and must meet the maximum and minimum voltage requirements. (see electrical specifications).

## MODE

Input. Pin 2. MODE determines the dialer's default operating mode. When the device is powered up or the hookswitch input is switched from on-hook, $\left(\mathrm{V}_{+}\right)$, to off-hook, ( $\mathrm{V}-$ ), the default determines the signaling mode. A V+ connection defaults to tone mode operation and a $V$ - connection defaults to pulse mode operation.
When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the * key, or softswitch, is depressed. Subsequent * key inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to offhook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.
$\overline{\mathrm{C} 1}, \overline{\mathrm{C} 2}, \overline{\mathrm{C} 3}, \overline{\mathrm{C} 4}, \overline{\mathrm{R} 4}, \overline{\mathrm{R} 3}, \overline{\mathrm{R} 2}, \overline{\mathrm{R} 1}$
Keyboard inputs. The MK53761 interfaces with either the standard $2-\mathrm{of}-8$ with negative common or the singlecontact (Form A) keyboard.
A valid keypad entry is either a single Row connected to a single Column or V-simultaneously presented to both a single Row and Column. In its quiescent or standby state, during normal off-hook operation, either the Rows or the Columns are at a logic level $1\left(V_{+}\right)$. Pulling one input low enables the on-chip oscillator. Keyboard scanning then begins. Scanning consists of Rows and Columns alternately switching high through on-chip pullups. After both a Row and Column key have been detected, the debounce counter is enabled and any noise (bouncing contacts, etc.) is ignored for a debounce period (Tкд) of 32 ms . At this time, the keyboard is sampled and if both Row and Column information are valid, the information is buffered into the LND location. If switched on-hook (pin 17 to pin 1), the keyboard inputs all pull high through on-chip pullup resistors.
In the tone mode, if 2 or more keys in the same row or if 2 or more keys in the same column are depressed a single tone will be output. The tone will correspond to the row or column for which the 2 keys were pushed. This feature is for test purposes, and single tones will not be redialed.
Also in the tone mode, the output tone is continuous is manual dialing as long as the key is pushed. The output tone duration follows the table 1 .

Table 1: Output Tone Duration.

| Key-Push Time, $\mathrm{T}^{*}$ | Tone Output ${ }^{\star}$ |
| :--- | :--- |
| $\mathrm{T} \leq 32 \mathrm{~ms}$ | No Output Ignored by <br> MK53761 |
| $32 \mathrm{~ms} \leq \mathrm{T} \leq 75 \mathrm{~ms}+\mathrm{T}_{\text {KD }}$ | 75 ms Duration Output |
| $\mathrm{T} \geq 75 \mathrm{~ms}+\mathrm{T}_{\text {KD }}$ | Output Duration $=$ <br> $\mathrm{T}-\mathrm{T}_{K D}$ |

* TKD is the key pad debounce time which is typically 32 ms .

When redialing in the tone mode, each DTMF output is 75 ms duration, and the tone separation (intersignal delay) is 50 ms .

V-
Input. Pin 6 is the negative supply input to the device. This is the voltage reference for all specifications.

OSC1, OSC2
Pin 7 (input), pin 8 (output). OSC1 and OSC2 are connections to an on-chip inverter used as the timing reference for the circuit. It has sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation from this standard is directly reflected in the Tone output frequencies. The crystal oscillator provides the time reference for all circuit functions. A ceramic resonator with tolerance of $\pm 0.25 \%$ may also be used.

## DTMF OUTPUT

Output. Pin 10. An NPN transistor emitter with a collector tied to $\mathrm{V}+$ drives the DTMF OUTPUT pin. The transistor base is connected to an on-chip operational amplifier that mixes the Row and Column tones. Figure 7 shows the timing at this pin.
The DTMF OUTPUT is the summation of a single Row frequency and a single Column frequency. A typical single tone sine wave is shown in Figure 4. This waveform is synthesized using a resistor tree with sinusoidally weighted taps.

The MK53761 is designed to operate from an unregulated supply ; the TONE LEVEL is supply independent, and the single row tone output level will be typically :

$$
\mathrm{T}_{\mathrm{oi}}=-12 \mathrm{dBm} \pm 1 \mathrm{~dB}
$$

The DC component of the DTMF output while active is described by the following equation :

$$
\mathrm{VDC}_{1}=0.3 \mathrm{~V}++0.5 \text { Volts }
$$

Figure 3 : MK53761 Functional Block Diagram.

Figure 4 : Typical Single Tone.

Figure 5 : Typical Dual Tone.

Figure 6 : Typical Spectral Response.

PACIFIER TONE OUTPUT/CHIP DISABLE INPUT
Output. Pin 11. The pacifier tone provides audible feed-back, confirming that the key has been proper-
ly entered and accepted. A 500 Hz square wave is activated upon acceptance of a valid key input, after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. In pulse mode, all key entries activate the pacifier tone. In tone mode, any non-DTMF key (LND, FLASH, MEM, PROG) entry activates the pacifier tone. When programming the chip, all valid key entries activate the pacifier tone in either pulse or tone mode.
The CHIP DISABLE is an input. When pin 11 is switched low through a resistor ( 10 K to 100 K ), the MK53761 is enabled. When pin 11 is switched to $V_{+}$ through the resistor, all keypad inputs are pulled high, and the MK53761 will ignore all keypad inputs. When the chip is disabled, it will not dial, and it cannot be programmed. The chip can only be disabled when the circuit is inactive (not dialing) and Pin 12 is switched high.

Table 2 : DTMF Output Frequency.

| Key Input |  | Standard Frequency | Actual Frequency |
| :---: | :---: | :---: | :---: |
| ROW | 1 | 697 | 699.1 |
|  | 2 | 770 | 766.2 |
|  | 852 | 847.4 | -0.31 |
|  | 3 | 941 | 948.0 |
| COL | 1 | 1209 | 1215.9 |
|  | 1336 | 1331.7 | -0.54 |
|  | 2 | 1477 | 1471.9 |

## MUTE OUTPUT

Output. Pin 12. This pin is the MUTE OUTPUT for both tone and pulse modes. Timing is dependent upon mode.
The MUTE OUTPUT consists of an open drain Nchannel device. During standby, the output is high impedance and generally has' an external pullup resistor to the positive supply.
In the tone mode, MUTE OUTPUT is used to remove the transmitter and the receiver from the network during DTMF signaling. During dialing, MUTE OUTPUT is active continuously until dialing is completed. MUTE OUTPUT goes active when any key is pushed.
In the pulse mode, MUTE OUTPUT is used to remove the receiver and the network from the line. Different circuitry is required for tone and pulse muting external to the IC and applications using both modes would not necessarily share circuitry. MUTE OUTPUT timing is shown in Figure 8 for pulse mode si-
gnaling and Figure 7 for tone mode signaling. $\overline{\text { MUTE }}$ OUTPUT is active during each digit, and not active during the interdigit time. In both tone and pulse modes, MUTE OUTPUT goes active 40 ms before PULSE OUTPUT for a FLASH. Figure 8 illustrates the timing for this pin.

## HKS

Input. Pin 17. Pin 17 is the hookswitch input to the MK53761. This is a high-impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input causes the on-chip logic to initialize, terminating any operation in progress at the time. The signaling mode defaults to the mode selected at pin 2.

## PULSE OUTPUT

Output. Pin 18. This is an output consisting of an open drain N -channel device. In either pulse or tone mode, the FLASH key will cause a 560 ms output pulse at pin 18.

Figure 7 : Tone Mode Timing.

Notes : 1. For this example, key entries are $\leq 75 \mathrm{~ms}$, but $\geq 32 \mathrm{~ms}$.
2. MUTE goes active after any key is depressed.

Figure 8 : Pulse Mode Timing..

## DEVICE OPERATION

When the MK53761 is not actively dialing, it consumes very little current. Row and Column inputs assume opposite states off-hook. The circuit verifies that a valid key has been entered by alternately scanning the Row and Column inputs. If the input is still valid following 32 ms of debounce, the digit is stored into memory, and dialing begins after a pre-signal delay of approximately 40 ms (measured from initial key closure). Output tone duration is shown in Table 1.
The MK53761 allows manual dialing of an indefinite number of digits, but if more than 18 digits are dialed per number, the 53761 will "wrap around". That is, the extra digits beyond 18 will be stored at the beginning of the LND buffer, and the first 18 digits will no longer be available for redial. During autodial from LND or any memory location, key inputs are not accepted, but they will suspend dialing until released.

NORMAL DIALING (off-hook)

Normal dialing is straightforward, all keyboard entries will be stored in the buffer and signaled in succession.

## LAST NUMBER DIALED (LND)

LND

Last number dialing is accomplished by entering the LND key.

## HOOK FLASH

...ETC

Hook flash may be entered into the dialed sequence at any point by keying in the function key, FLASH.

Flash consists of a timed Break of 560 ms . The FLASH function is stored in memory, but it will not be redialed as such. When a FLASH key is pressed, no further key inputs will be accepted until the hookflash function ( 560 ms break) has been dialed. The key input following a FLASH will be stored as the initial digit of a new number (overwriting the number dialed prior to the FLASH) unless it is another FLASH. Consecutive FLASH entries after a number is dialed will be stored sequentially in the LND memory and a subsequent LND entry will cause the redial of that number with a delay, but not hookflash breaks, at the end of the redialing sequence. When redialing in tone mode, MUTE OUTPUT will remain active during the flash delay period.

## SOFTSWITCH

When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the * key is depressed. Subsequent * key inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to off-hook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.

## PROGRAMMING AND REPERTORY DIALING

Programming is independent of HKS (pin 17) and MODE (pin 2).

To program, enter the following :
PROG, Digit 1, Digit 2, ..., MEM, Location (1-9).
When programming, dialing in inhibited.
To dail a number from repertory memory (HKS must be low) enter the following :

MEM, Location (1-9).
To save the last number dialed: PROG, MEM, Location (1-9).

Table 3 : Special Function Delays.
Each delay shown below represents the time required from after the special function key is depressed until a new digit can be dialed.
The time is considered "FIRST" key is all previous inputs have been completed dialed. The time is considered "AUTO" if in redial, or previous dialing is still in progress.

| Function | First/Auto | Delay (seconds) |  |
| :--- | :--- | :---: | :---: |
|  |  | Pulse | Tone |
| SOFTSWITCH | FIRST | 0.40 |  |
|  | AUTO | 1.10 |  |

## ABSOLUTE MAXIMUM RATINGS*

| Parameter | Value | Unit |
| :--- | :---: | :---: |

## REPERTORY DIALER

- SINGLE CHIP DTMF AND PULSE DIALER
- STORES 10 18-DIGIT TELEPHONE NUMBERS, INCLUDING LAST NUMBER DIALED
- SOFTSWITCH CHANGĖS SIGNALING MODE FROM PULSE TO TONE
- SINGLE BUTTON REDIAL OF ALL TEN MEMORIES
- FLASH KEY INPUT INITIATES TIMED HOOK FLASH
- 8 TONES PER SECOND DIALING IN TONE MODE AND 10 PPS IN PULSE MODE
- DTMF ACTIVE UNTIL KEY RELEASE
- MINIMUM DTMF DURATION/SEPARATION GUARANTEED ( $74 / 54 \mathrm{~ms}$ )
- PACIFIER TONE PROVIDES AUDIBLE INDICATION OF A VALID KEY INPUT FOR NONDTMF KEY ENTRIES
- POWERED FROM TELEPHONE LINE, LOW OPERATING VOLTAGE FOR LONG LOOP APPLICATIONS

## DESCRIPTION

The MK53762 is a Silicon Gate CMOS IC that provides necessary signals for either DTMF or loop disconnect (pulse) dialing. The MK53762 buffers up to 18 digits into memory that can be later redialed with a single key input. Up to nine repertory numbers may be stored. Users can store all 12 signaling keys and access several unique functions with single key entries. These functions include : Last Number Dialed (LND), Softswitch, Flash, and 9 memories. Figure 2 shows the keypad configuration.
A LND key input automatically redials the last number dialed, and the MEM keys provide single key access to all memory locations for auto-dialing.
The FLASH key simulates a 560 ms hook flash to transfer calls or to activate other special features provided by the PABX or a central office.
The PAUSE key allows the user to insert a delay in dialing for functions such as the pause in accessing an outside line when redialing from a PABX.
The PROG key provides an easy way to program a number into any memory location (MEM 1 - MEM 9) whether on-hook or off-hook.

Figure 1 : Pin Connection.

Figure 2 : Keypad Configuration.

M88MK53フ62-01

## FUNCTIONAL PIN DESCRIPTION

V+
Pin 1. $\mathrm{V}+$ is the positive supply for the circuit and must meet the maximum and minimum voltage requirements. (see Electrical Specifications).

## MODE

Input. Pin 2. MODE determines the dialer's default operating mode. When the device is powered up or the hookswitch input is switched from on-hook, ( $\mathrm{V}_{+}$), to off-hook, ( $\mathrm{V}-$ ), the default determines the signaling mode. A V+ connection defaults to tone mode operation and a V - connection defaults to pulse mode operation.
When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the * key, or softswitch, is depressed. Subsequent * key inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to offhook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.
$\overline{\mathrm{C} 1}, \overline{\mathrm{C} 2}, \overline{\mathrm{C} 3}, \overline{\mathrm{C} 4}, \overline{\mathrm{C} 5}, \overline{\mathrm{R} 5}, \overline{\mathrm{R} 4}, \overline{\mathrm{R} 3}, \overline{\mathrm{R} 2}, \overline{\mathrm{R} 1}$
Keyboard inputs. The MK53762 interfaces with either the standard 2-of-10 with negative common or the single-contact (Form A) keyboard.

A valid keypad entry is either a single Row connected to a single Column or V-simultaneously presented to both a single Row and Column. In its quiescent or standby state, during normal off-hook operation, either the Rows or the Columns are at a logic level $1(\mathrm{~V}+)$. Pulling one input low enables the on-chip oscillator. Keyboard scanning then begins. Scanning consists of Rows and Columns alternately switching high through on-chip pullups. After both a Row and Column key have been detected, the debounce counter is enabled and any noise (bouncing contacts, etc.) is ignored for a debounce period (TKD) of 32 ms . At this time, the keyboard is sampled and if both Row and Column information are valid, the information is buffered into the LND location. If switched on-hook (pin 19 to pin 1), the keyboard inputs all pull high through on-chip pullup resistors.

In the tone mode, if 2 or more keys in the same row or column are depressed a single tone will be output. The tone will correspond to the row or column for which the 2 keys were pushed. This feature is for test purposes.
Single tones will not be redialed.
Also in the tone mode, the output tone is continuous
in manual dialing as long as the key is pushed. The output tone duration follows the table below :

Table 1 : Output Tone Duration.

| Key-Push Time, $\mathbf{T}^{*}$ | Tone Output ${ }^{\star}$ |
| :--- | :--- |
| $\mathrm{T} \leq 32 \mathrm{~ms}$ | No output. Ignored by <br> MK53762. |
| $32 \mathrm{~ms} \leq \mathrm{T} \leq 75 \mathrm{~ms}+\mathrm{T}_{\mathrm{KD}}$ | 75 ms Duration Output. |
| $\mathrm{T} \geq 75 \mathrm{~ms}+\mathrm{T}_{\text {KD }}$ | Output Duration $=$ <br> $\mathrm{T}-\mathrm{T}_{K D}$ |

*Note : $T_{K 0}$ is the key pad debounce time which is typically 32 ms .
When redialing in the tone mode, each DTMF output is 75 ms duration, and the tone separation (intersignal delay) is 50 ms .

## V -

Input. Pin 7 is the negative supply input to the device. This is the voltage reference for all specifications.

## OSC1, OSC2

Pin 8 (input), pin 9 (output). OSC1 and OSC2 are connections to an on-chip inverter used as the timing reference for the circuit. It has have sufficient loop gain to oscillate when used with a low-cost television color-burst crystal. The nominal crystal frequency is 3.579545 MHz and any deviation from this standard is directly reflected in the Tone output frequencies. The crystal oscillator provides the time reference for all circuit functions. A ceramic resonator with tolerance of $\pm 0.25 \%$ may also be used.

## DTMF OUTPUT

Output. Pin 11. An NPN transistor emitter with a collector tied to $\mathrm{V}+$ drives the DTMF OUTPUT pin. The transistor base is connected to an on-chip operational amplifier that mixes the Row and Column tones. Figure 7 shows the timing at this pin.
The DTMF OUTPUT is the summation of a single Row frequency and a single Column frequency. A typical single tone sine wave is shown in Figure 4. This waveform is synthesized using a resistor tree with sinusoidally weighted taps.
The MK53762 is designed to operate from an unregulated supply ; the TONE LEVEL is supply independent, and the single row tone output level will be typically :

$$
\mathrm{T}_{\mathrm{oi}}=-12 \mathrm{dBm} \pm 1 \mathrm{~dB}
$$

The DC component of the DTMF output while active is described by the following equation:

$$
\mathrm{VDC}_{1}=0.3 \mathrm{~V}++0.5 \text { Volts }
$$

Figure 3 : MK53762 Functional Block Diagram.

Figure 4 : Typical Single Tone.

Figure 5 : Typical Dual Tone.

## PACIFIER TONE OUTPUT/CHIP DISABLE INPUT

Pin 12. PAC tone is an output. The pacifier tone provides audible feedback, confirming that the key has been properly entered and accepted. A 500 Hz square wave is activated upon acceptance of a valid key input, after the 32 ms debounce time. The square wave terminates after a maximum of 30 ms or when the valid key is no longer present. In pulse mode, all key entries activate the pacifier tone. In tone mode, any non-DTMF key (LND, FLASH, MEM, PROG) entry activates the pacifier tone. When programming the chip, all valid key entries activate the pacifier tone in either pullse or tone mode. The CHIP DISABLE is an input. When pin 12 is switched low through a resistor ( 10 K to 100 K ), the MK53762 is enabled. When pin 12 is switched to $\mathrm{V}_{+}$ through the resistor, all keypad inputs are pulled high, and the MK53762 will ignore all keypad inputs. When the chip is disabled, it will not dial, and it can-
Figure 7 : Tone Mode Timing.

Notes : 1. For this example, key entries are $\leq 75 \mathrm{~ms}$, but $\geq 32 \mathrm{~ms}$.
2. MUTE goes active after any key is depressed.

Figure 8 : Pulse Mode Timing.

Table 2 : DTMF Output Frequency.

| Key Input |  | Standard Frequency | Actual Frequency | \% Deviation |
| :---: | :---: | :---: | :---: | :---: |
| ROW | 1 | 697 | 699.1 | +0.31 |
|  | 2 | 770 | 766.2 | -0.49 |
|  | 3 | 852 | 847.4 | -0.54 |
|  | 4 | 941 | 948.0 | +0.74 |
| COL | 1 | 1209 | 1215.9 | +0.57 |
|  | 2 | 1336 | 1331.7 | -0.32 |
|  | 3 | 1477 | 1471.9 | -0.35 |

## MUTE OUTPUT

Output. Pin 13. This pin is the MUTE OUTPUT for both tone and pulse modes. Timing is dependent upon mode.
The MUTE OUTPUT consists of an open drain Nchannel device. During standby, the output is high impedance and generally has an external pullup resistor to the positive supply.
In the tone mode, MUTE OUTPUT is used to remove the transmitter and the receiver from the network during DTMF signaling. During dialing, MUTE OUTPUT is active continuously until dialing is completed. MUTE OUTPUT goes active when any key is pushed.
In the pulse mode, MUTE OUTPUT is used to remove the receiver and the network from the line. Different circuitry is required for tone and pulse muting external to the IC and applications using both modes
would not necessarily share circuitry. MUTE OUTPUT timing is shown in Figure 8 for pulse mode signaling and Figure 7 for tone mode signaling. MUTE OUTPUT is active during each digit, and not active during the interdigit time. In both tone and pulse modes, MUTE OUTPUT goes active 40 ms before PULSE OUTPUT for a FLASH.

## HKS

Input. Pin 19. Pin 19 is the hookswitch input to the MK53762. This is a high-impedance input and must be switched high for on-hook operation or low for off-hook operation. A transition on this input causes the on-chip logic to initialize, terminating any operation in progress at the time. The signaling mode defaults to the mode selected at pin 2. Figure 8 illustrates the timing for this pin.

## PULSE OUTPUT

Output. Pin 20. This is an output consisting of an open drain N -channel device. In either pulse or tone mode, the FLASH key will cause a 560 ms output pulse at pin 20.

## DEVICE OPERATION

When the MK53762 is not actively dialing, it consumes very little current. Row and Column inputs assume opposite states off-hook. The circuit verifies that a valid key has been entered by alternately scanning the Row and Column inputs. If the input is still valid following 32 ms of debounce, the digit is stored into memory, and dialing begins after a pre-signal delay of approximately 40 ms (measured from initial key closure). Output tone duration is shown in Table 1.
The MK53762 allows manual dialing of an indefinite number of digits, but if more than 18 digits are dialed per number, the 53762 will "wrap around". That is, the extra digits beyond 18 will be stored at the beginning of the LND buffer, and the first 18 digits will no longer be available for redial. During autodial from LND or any MEM location, key inputs are not accepted, but they will suspend dialing until released.

NORMAL DIALING (off-hook)
D $\quad \mathbf{D} \quad \mathbf{D} \quad$...ETC

Normal dialing is straightforward, all keyboard entries will be stored in the buffer and signaled in succession.

LAST NUMBER DIALED (LND)

Last number dialing is accomplished by entering the LND key.

## SOFTSWITCH

When dialing in the pulse mode, a softswitch feature will allow a change to the tone mode whenever the * key is depressed. Subsequent * inputs will cause the DTMF code for an * to be dialed. The softswitch will only switch from pulse to tone. After returning to on-hook and back to off-hook, the part will be in pulse mode. Redial by the LND key will repeat the softswitch.

HOOK FLASH

...ETC

Hook flash may be entered into the dialed sequence at any point by keying in the function key, FLASH. Flash consists of a timed Break of 560 ms . The FLASH function is stored in memory, but it will not be redialed as such. When a FLASH key is pressed, no further key inputs will be accepted until the hookflash function ( 560 ms break) has been dialed. The key input following a FLASH will be stored as the initial digit of a new number (overwriting the number dialed prior to the FLASH) unless it is another FLASH. Consecutive FLASH entries after a number is dialed will be stored sequentially in the LND memory and a subsequent LND entry will cause the redial of that number with a delay, but not hookflash breaks, at the end of the redialing sequence. When redialing in tone mode, MUTE OUTPUT will remain active during the flash delay period.

## PAUSE

D
...ETC

A Pause may be entered into the dialed sequence at any point by keying in the special function key, PAUSE. Pause inserts a 1.1 -second delay into the dialing sequence. The total delay, including pre-digital and post-digital pauses is shown in Table 3.

## PROGRAMMING AND REPERTORY DIALING

PROGRAMMING AND REPERTORY DIALING
Programming is independent of HKS (pin 19) and MODE (pin 2).
To program, enter the following :
PROG, Digit 1, Digit 2, ..., MEM (Location 1-9). When programming, dialing is inhibited.
To dial a number from repertory memory (HKS must be low) enter the single key :
MEM (Location 1-9)
To save the last number dialed : PROG, MEM (Location 1-9).

Table 3 : Special Function Delays.
Each delay shown below represents the time required from after the special function key is depressed until a new digit can be dialed.
The time is considered "FIRST" key is all previous inputs have been completed dialed. The time is considered "AUTO" if in redial, or if previous dialing is still in progress.

| Function | First/Auto |  | Delay (seconds) |  |
| :--- | :--- | :---: | :---: | :---: |
|  |  | Pulse | Tone |  |
| SOFTSWITCH | FIRST | 0.40 | - |  |
|  | AUTO | 1.10 | - |  |
| PAUSE | FIRST | 1.84 | 1.15 |  |
|  | AUTO | 2.50 | 1.20 |  |

## ABSOLUTE MAXIMUM RATINGS *

## REPERTORY WORLD DIALER™

ADVANCE DATA

- STORAGE OF THIRTEEN 18-DIGIT NUMBERS : 3 EMERGENCY LOCATIONS, AND 10 ADDITIONAL LOCATIONS INCLUDING LNR (last number redial)
- ALL LOCATIONS CAN BE ACCESSED WITH SINGLE KEY INPUTS ALTHOUGH THE OPTION IS AVAILABLE TO ACCESS 3 EMERGENCY LOCATIONS PLUS LNR DIRECTLY AND TWOKEYS (MEM key plus key 1-9) TOACCESS THE 9 OTHER MEMORIES
- TWO SELECT PINS ALLOW USERTO SELECT 16 DIFFERENT COUNTRY OPTIONS
- SINGLE CHIP, MIXED MODE DIALER ALLOWS DIALING IN EITHER TONE OR PULSE MODES. A * OR "SOFTSWITCH" KEY INPUT CAN ALSO BE USED TO SWITCH FROM PULSE TO TONE MODE OPERATION AND IS STORED IN MEMORY
- P.I.N. (personal identity number) PROTECTION METHOD
- SLIDING CURSOR METHOD TO SIMPLIFY PABX DIALING
- HOOKSWITCH DEBOUNCE, TRANSIENTS DUE TO LINE REVERSALS AND DROP-OUTS CAN BE MASKED FOR A PERIOD DETERMINED BY EXTERNAL RC
- POWERED FROM TELEPHONE LINE, LOW STANDBY CURRENT AND OPERATING VOLTAGE
-•DTMF SIGNAL CONSISTENT WITH KEY ENTRY PERIOD
- MINIMUM DTMF SIGNAL DURATION/SEPARATION GUARANTEED
- TIMED PABX PAUSE MAY BE STORED IN MEMORY
- TIMED FLASH FOR EXTENDED TIMED BREAK

## DESCRIPTION

The MK53763 is a 24 pin CMOS mixed mode dialer IC. This dialer provides signalling for both TONE

(DTMF) and PULSE (LD) modes of operation and it stores up to 1318 -digit numbers including the last number dialed. The user can store all 12 signalling digits plus access several unique functions with single key entries. These functions include : Last Number Dialed (LND), Softswitch, Flash, Pause and 12 memories (M1-M9 and E1-E3).
The MK53763 can be switched from PULSE to TONE mode operation through the keypad with a * key input or softswitch (SS) key input. All key inputs following a softswitch command will generate DTMF signals.
Two select pins (SELA, SELB) have been provided which allow the part to be customized for various markets. Rather than selecting and modifying individual parameters which would take many pins or mask options each select pin will select groups of options which have been identified for particular markets.
The MK53763 features a sliding cursor, auto-pause insertion (on some options), manual Pause, and Flash. The DTMF tone output has a guarenteed minimum duty cycle and extends to match the duration of key inputs.
The MK53763 structure and specification are the same of the MK53721 LND world dialer, expanded with 3 emergency and 9 repertory numbers.

## LOW VOLTAGE TELEPHONE SPEECH CIRCUIT

ADVANCE DATA

- OPERATION DOWN TO $1.3 \mathrm{~V} / 5 \mathrm{~mA}$
- DTMF \& BEEP TONE INPUTS
- EXTERNAL MUTING FOR EARPHONE AND MICROPHONE
- MUTE TURNS ON BEEP TONE \& DTMF INPUTS AND TURNS OFF EARPHONE \& MICROPHONE
- SUITABLE FOR DYNAMIC OR PIEZO EARPHONES AND PIEZO, DYNAMIC OR ELECTRET MICROPHONES

## DESCRIPTION

The L3280 is a brand new low voltage speech circuit designed to replace hybrid circuits in telephone sets. It is designed for sets that may be operated in parallel. If features both DTMF input and Beep tone input ; ALC on send and receive and muting input.
Various DC - characteristics can be programmed at pin 14 replacing testing resistor ( $43 \Omega$ ) with pro-. per network value.

# TELEPHONE SPEECH CIRCUIT WITH MULTIFREQUENCY TONE GENERATOR INTERFACE 

- PRESENTS THE PROPER DC PATH FOR THE LINE CURRENT.
- HANDLES THE VOICE SIGNAL, PERFORMING THE $2 / 4$ WIRES INTERFACE AND CHANGING THE GAIN ON BOTH SENDING AND RECEIVING AMPLIFIERS TO COMPENSATE FOR LINE ATTENUATION BY SENSING THE LINELENGTH THROUGH THELINE CURRENT.
- ACTS AS LINEAR INTERFACE FOR MF, SUPPLYING A STABILIZED TO THE DIGITAL CHIP and delivering to the line the mF TONES GENERATED BY THE M761.

## DESCRIPTION

The LS156 is a monolithic integrated circuit in 16lead dual in-line plastic package to replace the hybrid circuit in telephone set. It works with the same type of transducers for both transmitter and receiver (typically piezoceramic capsules, but the device can work also with dynamic ones). Many of its electrical

characteristics can be controlled by means of external components to meet different specifications.
In addition to the speech operation, the LS156 acts as an interface for the MF tone signal (particularly for M761 C/MOS frequency synthesizer).

## CIRCUIT DESCRIPTION

## 1. DC CHARACTERISTIC

In accordance with CCITT recommendations, any device connected to a telephone line must exhibit a proper DC characteristics $\mathrm{V}_{\mathrm{L}}, \mathrm{L}$.
The DC characteristic of the LS156 it is determined by the shunt regulator (block 2) together with two series resistors $R_{1}$ and $R_{3}$. The equivalent circuit of the total system is shown in fig. 5 .
A fixed amount $I_{0}$ of the total available current $I_{L}$ is drained for the proper operation of the circuit. The value of $l_{0}$ can be programmed externally by changing the value of the bias resistor connected to pin 4 (see block diagram).
The recommended minimum of $\mathrm{I}_{0}$ is 7.5 mA .
The voltage $\mathrm{Vo} \cong 3.8 \mathrm{~V}$ of the shunt regulator is independent of the line current.

The shunt regulator (2) is controlled by a temperature compensated voltage reference (1) (see the block diagram).

Fig. 6 shows a more detailed circuit configuration of the shunt regulator.

The difference $I_{L}-I_{0}$ flows through the shunt regulator being $\mathrm{l}_{\mathrm{b}}$ negligible.
$\mathrm{l}_{\mathrm{a}}$ is an internal constant current generator ; hence $\mathrm{V}_{\mathrm{o}}=\mathrm{V}_{\mathrm{BED} 1}+\mathrm{l}_{\mathrm{a}} \cdot \mathrm{R}_{\mathrm{a}} \cong 3.8 \mathrm{~V}$. The $\mathrm{V}_{\mathrm{L}}, \mathrm{l}_{\mathrm{L}}$ characteristic of the device is therefore similar to a pure resistance in series to a battery.
It is important to note that the DC voltage at pin 5 is proportional to line current $\left(\mathrm{V}_{5}=\mathrm{V}_{7}+\mathrm{V}_{\mathrm{BED}} \cong\left(\mathrm{lL} \cdot \mathrm{I}_{0}\right)\right.$ $R_{3}+V_{B E D 1}$ ).

Figure 5 : Equivalent DC Load to the Line.

Figure 6 : Circuit Configuration of the Shunt Regulator.

## 2. 2/4 WJRES CONVERSION

The LS156 performs the two wires (line) to four wires (microphone, earphone) conversion by means of a Wheatstone bridge configuration so obtaining the proper decoupling between sending and receiving signals (see fig. 7).
For a perfect balancing of the bridge $\frac{\mathrm{Z}_{\mathrm{L}}}{\mathrm{Z}_{\mathrm{B}}}=\frac{\mathrm{R}_{1}}{\mathrm{R}_{2}}$
The AC signal from the microphone is sent to one diagonal of the bridge (pin 6 and 9). A small percentage of the signal power is lost on $\mathrm{Z}_{\mathrm{B}}$ (being $\left.Z_{B} \gg Z_{L}\right)$; the main part is sent to the line via $R_{1}$.
In receiving mode, the AC signal coming from the line is sensed across the second diagonal of the bridge (pin 11 and 10). After amplification it is applied to the receiving capsule.
The impedance $\mathrm{Z}_{\mathrm{M}}$ is simulated by the shunt regulator that is also intended to work as a transconductance amplifier for the transmission signal.
The impedance $\mathrm{Z}_{\mathrm{M}}$ is defined as $\frac{\Delta \mathrm{V}_{6-9}}{\Delta \mathrm{l}_{6-9}}$.
From fig. 6, considering $C_{1}$ as a short circuit for AC signal, any variation $\Delta \mathrm{V}_{6}$ generates a variation.

$$
\Delta \mathrm{V}_{7}=\Delta \mathrm{V}_{\mathrm{A}}=\Delta \mathrm{V}_{6} \cdot \frac{\mathrm{R}_{\mathrm{b}}}{\mathrm{R}_{\mathrm{a}}+\mathrm{R}_{\mathrm{b}}}
$$

The corresponding current change is

$$
\Delta \mathrm{l}=\frac{\Delta \mathrm{V}_{7}}{\mathrm{R}_{3}}
$$

Therefore

$$
Z_{M}=\frac{V_{6}}{D I}=R_{3}\left(1+\frac{R_{a}}{R_{b}}\right)
$$

The total impedance across the line connections (pin 11 and 9 ) is given by

$$
Z_{M L}=R_{1}+Z_{M} / /\left(R_{2}+Z_{B}\right)
$$

By choosing $Z_{M} \gg R_{1}$ and $Z_{B} \geq Z_{M}$

$$
\mathrm{Z}_{\mathrm{ML}} \cong \mathrm{Z}_{\mathrm{M}}=\mathrm{R}_{3}\left(1+\frac{\mathrm{R}_{\mathrm{a}}}{\mathrm{R}_{\mathrm{b}}}\right)
$$

The received signal amplitude across pin 11 and 10 can be changed using different values of $R_{1}$ (of course the relationship $\frac{\mathrm{Z}_{\mathrm{L}}}{\mathrm{Z}_{\mathrm{B}}}=\frac{\mathrm{R}_{1}}{\mathrm{R}_{2}}$ must be always valid).

The received signal is related to $R_{1}$ value according to the approximated relationship

$$
\mathrm{V}_{\mathrm{R}}=2 \cdot \mathrm{~V}_{\mathrm{RI}} \quad \frac{\mathrm{R}_{1}}{\mathrm{R}_{1}+\mathrm{Z}_{\mathrm{M}}}
$$

Note that by changing the value of $R_{1}$, the transmission signal current is not changed, being the microphone amplifier a transconductance amplifier.

Figure 7 : Two to Four Wires Conversion.

## 3. AUTOMATIC GAIN CONTROL

The LS156 automatically adjusts the gain of the sending and receiving amplifiers to compensate for line attenuation by sensing the line length through the line current.

The line current is sensed across $\mathrm{R}_{3}$ (see fig. 6) and transferred to pin 5 by the regulator.

$$
V_{5}=V_{B E D 1}+V_{7} \cong V_{B E D 1}+\left(I_{L}-I_{0}\right) \cdot R_{3} .
$$

The pin $5 \mathrm{~V}_{5}$ voltage, after a comparison with an internal reference $\mathrm{V}_{\text {REFG }}$ (see the block diagram) is used to modify the gain of the amplifiers (4) and (5) on both the sending and receiving path.
The starting point of the automatic level control is obtained at $\mathrm{l}=25 \mathrm{~mA}$ when the drain current $\mathrm{l}_{\mathrm{o}}=$ 7.5 mA .

Minimum gain is reached for a line current of about 52 mA for the same drain current $\mathrm{l}_{0}=7.5 \mathrm{~mA}$.

When $\mathrm{I}_{0}$ is increased by means of the external resistor connected to pin 4, the two above mentioned values of the line current for the starting point and. for the minimum gain increase accordingly :
Automatic switching of the balance network $\mathrm{Z}_{\mathrm{B}}$ for a better sidetone is performed by the LS156 through $\mathrm{V}_{5}$ information. This information, proportional to the line length, drives the comparator (7 b) (see the block diagram).
For long lines, the impedance level of $Z_{B}$ is high (pin 8 open) and the additional +1 dB gain is added to the receiving amplifier chain.
For short lines, the impedance level of $Z_{B}$ is automatically switched to a lower value (pin 8 shorted to ground) and the additional +1 dB block is bypassed by the received signal.
A built in hysteresis circuit avoids uncertain operation of the comparator.

## 4. TRANSDUCERS INTERFACING

The microphone amplifier (3) has a differential input stage with high impedance ( $\cong 40 \mathrm{k} \Omega$ ) so allowing a good matching to the microphone by means of external resistors without affecting the sending gain.
The receiving output stage (6) is particularly intended to drive piezoceramic capsules. [Low output im-
pedance (100 $\Omega$ max) ; high voltage swing (close to $\mathrm{V}_{\mathrm{L}}$ ) ; current capability of 1.8 mAp ].
When a dynamic capsule is used, it is useful to decrease the receiving gain by decreasing $R_{1}$ value (see the relationship for $\mathrm{V}_{\mathrm{R}}$ ).
With very low impedance transducer, DC decoupling by an external capacitor must be provided to prevent a large DC current flow across the transducer itself due to the receiving output stage offset.

## 5. MULTIFREQUENCY INTERFACING

The LS156 acts a linear interface for the Multifrequency synthesizer M761 according to a logical signal (mute function) present on pin 3.
When no key of the keyboard is pressed the mute state is low and the LS156 feeds the M761 through pin 15 with low current (standby operation of the M761). The oscillator of the M761 is not operating. When one key is pressed, the M761 sends a "high state" mute condition to the LS156. A voltage comparator (9) of LS156 drives internal electronic switches : the current delivered by the voltage supply (10) is increased to allow the operation of the oscillator. This extra current is diverted by the receiving and sending section of the LS156 and during this operation the receiving output stage is partially inhibited and the input stages of sending and receiving amplifiers are switched OFF.

A controlled amount of the signalling is allowed to reach the earphone to give a feedback to the subscriber ; the MF amplifier (11) delivers the dial tones to the sending paths.

The application circuit shown in fig. 9 fulfils the EUROPE II standard $(-6,-8 \mathrm{dBm})$. If the EUROPE I levels are required ( $-9,-11 \mathrm{dBm}$ ), an external divider must be used (fig. 11).
The mute function can be used also when a temporary inhibition of the output signal is requested.

## APPLICATION INFORMATION

The circuits shown in fig. 8 and fig. 11 are referred to the Italian standard. The fig. 10 shows the connection for mute function (inhibition of the output stage when it is requested) by using an external switch at pin 3.

## APPLICATION INFORMATION (continued)

| Component | Value | Purpose | Note |
| :---: | :---: | :---: | :---: |
| $\mathrm{R}_{1}$ | $68 \Omega$ | Bridge Resistors | $\mathrm{R}_{1}$ controls the receiving gain. <br> The Ratio $R_{2} / R_{1}$ fixes the amount of signal delivered to the line. $\mathrm{R}_{1}$ helps in fixing the $D C$ characteristic (see $\mathrm{R}_{3}$ note). |
| $\mathrm{R}_{2}$ | $330 \Omega$ |  |  |
| $\mathrm{R}_{3}$ | $30 \Omega$ | Line Current Sensing. Fixing DC Characteristics | The relationships involving $R_{3}$ are: <br> - $Z_{M L}=\left(20 R_{3} / / Z_{B}\right)+R_{1}$ <br> - $G_{S}=K \cdot \frac{Z_{L} / / Z_{M L}}{R_{3}}$ <br> - $\mathrm{V}_{\mathrm{L}}=\left(\mathrm{I}_{\mathrm{L}}-\mathrm{I}_{0}\right)\left(\mathrm{R}_{3}+\mathrm{R}_{1}\right)+\mathrm{V}_{0} ; \mathrm{V}_{0}=3.8 \mathrm{~V}$. <br> Without any problem it is possible to have a $\mathrm{Z}_{\mathrm{ML}}$ ranging from 500 up to $900 \Omega$. |
| $\mathrm{R}_{4}$ | $13 \mathrm{k} \Omega$ | Bias Resistor | The suggested value assures the minimum operating current. It is possible to increase the supply current by decreasing $\mathrm{R}_{4}$ (they are inversely proportional), in order to achieve the shifting of the AGC starting point. (see fig. 12). |
| $\mathrm{R}_{5}$ | $7.5 \mathrm{k} \Omega$ | Balance Network | The balance network has two possible impedance levels, selected by the circuit referring to the line current (i.e. to the line length) in order to optimize the sidetone. It's possible to change $\mathrm{R}_{5}, \mathrm{R}_{6}, \mathrm{R}_{7}$ values in order to improve the matching to different lines; in any case: <br> $\frac{Z_{B}}{Z_{L}}=\frac{R_{2}}{R_{1}}$ with the two possible values for $Z_{B}$ : $\begin{aligned} & Z_{B(1)}=R_{7}+R_{6} / / C_{4} \text { (long lines) } \\ & Z_{B(2)}=R_{7}+\left(R_{6} / / R_{5}\right) / / C_{4} \text { (short lines) } \\ & \text { (see fig. } 13 \text { ). } \end{aligned}$ |
| $\mathrm{R}_{6}$ | $5.1 \mathrm{k} \Omega$ |  |  |
| $\mathrm{R}_{7}$ | $1 \mathrm{k} \Omega$ |  |  |
| $\mathrm{R}_{8}-\mathrm{R}_{8}{ }^{\prime}$ | $1.8 \mathrm{k} \Omega$ | Receiver Impedance Matching | $R_{8}$ and $R_{8}{ }^{\prime}$ must be equal; the suggested value is good for matching to piezoceramic capsule; there is no problem in increasing and decreasing (down to $0 \Omega$ ) this value, but when low resistance levels are used a DC decoupling must be inserted to stop the current due to the receiver output offset voltage (max 400 mV ). |
| $\mathrm{R}_{9}$ | 3.6 k $\Omega$ | Microphone Impedance Matching | The suggested value is typical for a piezoceramic microphone, but it is possible to choose $\mathrm{R}_{9}$ in a wide range. |
| $\mathrm{C}_{1}$ | $10 \mu \mathrm{~F}$ | Regulator AC Bypass | A value greater than $10 \mu \mathrm{~F}$ gives a system start time too high for low current line during MF operation; a lower, value gives an alteration of the $A C$ line impedance at low frequency |
| $\mathrm{C}_{2}$ | 47 nF | Matching to a Capacitive Line | $\mathrm{C}_{2}$ changes with the characteristics of the transmission line. |
| $\mathrm{C}_{3}$ | 82 nF | Receiving Gain Flatness | $\mathrm{C}_{3}$ depends on balancing and line impedance versus frequency. |
| $\mathrm{C}_{4}$ | 22 nF | Balance Network | See Note for $\mathrm{R}_{7}^{\prime}, \mathrm{R}_{6}, \mathrm{R}_{5}$. |
| $\mathrm{C}_{5}$ | $0.33 \mu \mathrm{~F}$ | DC Filtering | The $\mathrm{C}_{5}$ range is from $0.1 \mu \mathrm{~F}$ to $0.47 \mu \mathrm{~F}$. The lowest value is ripple limited, the higher value is starting up time limited. |
| $\mathrm{C}_{6}-\mathrm{C}_{7}$ | 1000 pF | RF Bypass |  |
| $\mathrm{C}_{8}$ | $1 \mu \mathrm{~F}$ | Dc Decoupling for Receiving Input | The DC offset is very low. An electrolitic capacitor can be used. |

ADVANCE DATA

- PRESENTS THE PROPER DC PATH FOR THE LINE CURRENT
- HANDLES THE VOICE SIGNAL, PERFORMING THE $2 / 4$ WIRES INTERFACE AND CHANGING THE GAIN ON BOTH SENDING AND RECEIVING AMPLIFIERS TO COMPENSATE FOR LINE ATTENUATION BY SENSING THE LINE LENGTH THROUGH THE LINE CURRENT
- ACTS AS LINEAR INTERFACE FOR MF, SUPPLYING A STABILIZED TO THE DIGITAL CHIP AND DELIVERING TO THE LINE THE MF TONE GENERATED BY THE DIALER

## DESCRIPTION

The LS256 is a monolithic integrated circuit in 16lead dual in-line plastic package to replace the hybrid circuit in telephone set. It works with the same type of transdurcers for both transmitter and receiver (typically piezoceramic capsules, but the device

can work also with dynamic ones). Many of its electrical characteristics can be controlled by means of external components to meet different specifications.
In addition to the speech operation, the LS256 acts as an interface for the MF tone signal.

## TELEPHONE SPEECH CIRCUITS

- 2/4 WIRE INTERFACE
- OPERATES DOWN TO 4 mA
- $3.5 \mathrm{~V}_{\mathrm{pp}}$ DYNAMIC IN SENDING AT 25 mA

## DESCRIPTION

The LS285 is monolithic integrated circuits for replacement of the hybrid circuit ( $2-4$ wire interface) in conventional telephones interfacing the two transducers to the line and providing a controlled amount of sidetone.
The same type of transducer can be used for both transmitter and receiver, usually a $350 \Omega$ dynamic type.
By sensing the line current, LS285 adjusts the gain in both directions to compensate for line attenuation.
Output impedance can be matched to the line, independent of transducer impedance.
The LS285 is packaged in a 14 lead dual in-line plastic package.

## DESCRIPTION

The LS285 is based on a bridge configuration.
They contain a regulator block, a sending amplifier and a receiver amplifier.
The regulator monitors the line current and adjusts the amplifier gain to compensate for the line length. It provides DC characteristics in line with CEPT standards.
The transmit/receiver amplifiers are connected to the line via an external bridge to provide sidetone attenuation.
The line current compensation ensures that when the subscriber is talking, the signal delivered to the line is increased in according to the line lenght. When he is hearing, the signal level on the receiver capsule is constant.
The amplifiers can also be matched to different transducers simply by varying external components. Gain variation over the operating temperature range is less than $\pm 1 \mathrm{~dB}$.

The impedance to the line can be adjusted ; without any change in circuit parameters ; by changing an external resistor ( $6.8 \mathrm{~K} \Omega$ at pin 2).

Figure 6 : Typical Application Circuit.

## APPLICATION INFORMATION

The following table shows the recommended values for the typical application circuit of fig. 6. Different values can be used and notes are added in order to help designer.

| Component | Recommended Value | Purpose | Note |
| :---: | :---: | :---: | :---: |
| R1 | $75 \Omega$ | Bridge Resistors | The ratio R2/R1 fixes the amount of the signal delivered to the line. (see fig. 7) |
| R2 | $536 \Omega$ |  |  |
| R3 | $16.2 \mathrm{~K} \Omega$ | Bias Resistor | Changing R3 value it is possible to shift the gain characteristics. <br> The value can be chosen from $15 \mathrm{~K} \Omega$ to $20 \mathrm{~K} \Omega$. The recommended value assures the maximum swing (see fig. 9). |
| R4 | $2.05 \mathrm{~K} \Omega$ | Balance Network | In order to optimize the sidetone it is possible to change R4 and R5 values. In any case :$\frac{\mathrm{Z}_{\mathrm{B}}}{\mathrm{Z}_{\mathrm{L}}}=\frac{\mathrm{R} 2}{\mathrm{R} 1} \text { where } \mathrm{Z}_{\mathrm{B}}=\mathrm{R} 4+\mathrm{R} 5 / / \mathrm{C} 4 .$ |
| R 5 | $9.09 \mathrm{~K} \Omega$ |  |  |
| R6 and R6' | $250 \Omega$ | Microphone Impedance Matching | R6 and R6' must be equal ; $250 \Omega$ is a typical value for dynamic capsules. <br> Furthermore, they determine a sending gain variation according to : $\Delta G_{s}=20 \log \frac{\mathrm{RX}}{850 \Omega}$ <br> where $R x=R 6+R 6^{\prime}+R_{\text {mike }}$. The trend of $\Delta G_{s}$ as a function of $R x$ value is shown in fig. 8. |
| R7 and R7' | $100 \Omega$ | Receive Impedance Matching | R7 and R7' must be equal ; $100 \Omega$ is a typical value for dynamic capsules. |
| C1 | $10 \mu \mathrm{~F}$ | AC Loop Opening | Ensures a high regulator impedance for AC signals ( $\approx 20 \mathrm{~K} \Omega$ ). <br> This capacitor should not be higher than $10 \mu \mathrm{~F}$ in order to have a short response time of the system. |
| C2 | 22 nF | Matching to a Capacitive Line | C2 changes with the characteristics of the transmission line. |
| C3 | 82 nF | High Frequency Roll-off | C3 determines the high frequency response of the circuit. <br> it also acts as RF bypass. |
| C4 | 22 nF | Balance Network | See Note for R4 and R5. |
| C5 | $1 \mu \mathrm{~F}$ | DC decoupling for Receiving Input |  |
| C6 and C7 | 1000 pF | RF Bypass |  |
| C8 | 22 nF | Filter Capacitor |  |

## TELEPHONE SPEECH CIRCUIT WITH MULTIFREQUENCY TONE GENERATOR INTERFACE

- PRESENTS THE PROPER DC PATH FOR THE LINE CURRENT
- HANDLES THE VOICE SIGNAL, PERFORMING THE $2 / 4$ WIRES INTERFACE AND CHANGING THE GAIN ON BOTH SENDING AND RECEIVING AMPLIFIERS TO COMPENSATE FOR LINE ATTENUATION BY SENSING EITHER THE LINE CURRENT OR THE LINE VOLTAGE. IN ADDITION, THE LS356 CAN ALSO WORK IN FIXED GAIN MODE
- ACTS AS LINEAR INTERFACE FOR MF, SUPPLYING A STABILIZED VOLTAGE TO THE DIGITAL CHIP AND DELIVERING TO THE LINE THE MF TONES GENERATED BY THE M761

## DESCRIPTION

The LS356 is a monolithic circuit in 16-lead dual inline plastic package to replace the hybrid circuit in telephone set. It works with the same type of transducers for both transmitter and receiver (typical dy-

namic capsules, but the device can also work with piezoceramic ones). Many of its electrical characteristics can be controlled by means of external components to meet different specifications.

In addition to the speech operation, the LS356 acts as an interface for the MF tone signal (particularly for M761 C/MOS frequency synthesizer).

## CIRCUIT DESCRIPTION

## 1. DC CHARACTERISTIC

The fig. 5 shows the DC equivalent circuit of the LS356.
Figure 5 : Equivalent DC Load to the Line.

A fixed amount $l_{0}$ of the total available current $I_{L}$ is drained for the proper operation of the circuit.
The value of $l_{0}$ can be programmed externally by changing the value of the bias resistor connected to pin 4 (see block diagram).

The voltage $\mathrm{V}_{0}=3.8 \mathrm{~V}$ of the shunt regulator is independent of the line current.
The shunt regulator (2) is controlled by a temperature compensated voltage reference (1) (see the block diagram).

The minimum value of $\mathrm{I}_{0}$ is 7.5 mA .

Fig. 6 shows a more detailed circuit configuration of the shunt regulator.
Figure 6 : Circuit Configuration of the Shunt Regulator.

The difference $L_{L}-I_{0}$ flows through the shunt regulator being $\mathrm{l}_{\mathrm{b}}$ negligible.
$\mathrm{l}_{\mathrm{a}}$ is an internal constant current generator ; hence $\mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{B}}+\mathrm{l}_{\mathrm{a}} \cdot \mathrm{R}_{\mathrm{a}}=3.8 \mathrm{~V}$.
The $\mathrm{V}_{\mathrm{L}}, \mathrm{I}_{\mathrm{L}}$ characteristic of the device is therefore similar to a pure resistance in series to a battery.
It is important to note that the DC voltage at pin 5 is proportional to the line current $\left(V_{5}=V_{7}+V_{B}=\right.$ $\left.\left(I_{L}-I_{0}\right) R 3+V_{B}\right)$.

## 2. TWO TO FOUR WIRES CONVERSION

The LS356 performs the two wires (line) to"four wires (microphone, earphone) conversion by means of a Wheatstone bridge configuration so obtaining the proper decoupling between sending and receiving signals (see fig. 7).
For a perfect balancing of the bridge $\frac{\mathrm{Z}_{\mathrm{L}}}{\mathrm{Z}_{\mathrm{B}}}=\frac{\mathrm{R} 1}{\mathrm{R} 2}$.
The AC signal from the microphone is sent to one diagonal of the bridge (pin 6 and 9). A small percentage of the signal power is lost on $\mathrm{Z}_{\mathrm{B}}$ (being $\left.Z_{B} \gg Z_{L}\right)$; the main part is sent to the line via $R 1$.
In receiving mode, the AC signal coming from the line is sensed across the second diagonal of the bridge (pin 11 and 10). After amplification it is applied to the receiving capsule.

The impedance $Z_{M}$ is simulated by the shunt regulator that is also intended to work as a transconductance amplifier for the transmission signal.
The impedance $Z_{M}$ is defined as $\frac{\Delta V_{6-9}}{\Delta \mathrm{I}_{6-9}}$.
From fig. 6 considering C 1 as a short circuit for AC signal, any variation $\Delta V_{6}$ generates a variation :

$$
\Delta \mathrm{V}_{7}=\Delta \mathrm{V}_{\mathrm{A}}=\Delta \mathrm{V}_{6} \cdot \frac{\mathrm{R}_{\mathrm{b}}}{\mathrm{R}_{\mathrm{a}}+\mathrm{R}_{\mathrm{b}}}
$$

The corresponding current change is

$$
\Delta I=\frac{\Delta V_{7}}{R 3}
$$

Therefore

$$
Z_{M}=\frac{\Delta V_{6}}{\Delta l}=R 3\left(1+\frac{R_{a}}{R_{b}}\right)
$$

The total impedance across the line connections (pin 11 and 9 ) is given by

$$
\mathrm{Z}_{\mathrm{ML}}=\mathrm{R} 1+\mathrm{Z}_{\mathrm{M}} / /\left(\mathrm{R} 2+\mathrm{Z}_{\mathrm{B}}\right)
$$

By choosing $Z_{M} \gg R 1$ and $Z_{B}>Z_{M}$

$$
Z_{M L} \cong Z_{M}=R 3\left(1+\frac{R_{\mathrm{a}}}{R_{\mathrm{b}}}\right)
$$

The received signal amplitude across pin 11 and 10 can be changed using different values of R1 (of course the relationship $\mathrm{Z}_{\mathrm{L}} / \mathrm{Z}_{\mathrm{B}}=\mathrm{R} 1 / \mathrm{R} 2$ must be always valid).

Figure 7 : Two to Four Wires Conversion.

The received signal is related to R1 value according to the approximated relationship :

$$
V_{R}=2 V_{\mathrm{RI}} \frac{\mathrm{R} 1}{\mathrm{R} 1+\mathrm{Z}_{\mathrm{M}}}
$$

Note that by changing the value of R1, the transmission signal current is not changed, being the microphone amplifier a transconductance amplifier.

## 3. AUTOMATIC GAIN CONTROL

The LS356 automatically adjusts the gain of the sending and receiving amplifiers to compensate for line attenuation.
This function is performed by the circuit of fig. 8.
The differential stage is progressively unbalanced by changing $\mathrm{V}_{\mathrm{G}}$ in the range 1 to 2 V ( $\mathrm{V}_{\mathrm{REFG}}$ is an internal reference voltage, temperature compensated).
It changes the current $\mathrm{IG}_{\mathrm{G}}$, and this current is used as a control quantity for the variable gain stages (amplifier (4) and (5) in the block diagram). The voltage $V_{G}$ can be taken :
a) from the LS356 itself (both in variable and in fixed mode) and
b) from a resistive divider, directly at the end of the line.
a) In the first case, connecting $\mathrm{V}_{\mathrm{G}}$ (pin 8) to the regulator bypass (pin 5 ) it is possible to obtain a
gain charcteristic depending on the current. In fact (see fig. 6) :

$$
V_{5}=V_{B}+V_{7} \cong V_{B}+\left(I_{L}-I_{0}\right) R 3
$$

The starting point of the automatic level control is obtained at $\mathrm{L}=25 \mathrm{~mA}$ when the drain current $\mathrm{I}_{0}=7.5 \mathrm{~mA}$.
Minimum gain is reached for a line current of about 52 mA for the same drain current $\mathrm{I}_{0}=7.5 \mathrm{~mA}$. When $\mathrm{I}_{0}$ is increased by means of the external resistor connected to pin 4, the two above mentioned values of the line current for the starting point and for the minimum gain increase accordingly.
It is also possible to change the starting point without changing $l_{0}$ by connecting pin 8 to the centre of a resistive divider placed between pin 5 and ground (the total resistance seen by pin 5 must be at least $100 \mathrm{~K} \Omega$ ). In this case, the AGC range increases too ; for example using a division 1:1 ( 50 K/50 K) the AGC starting point shifts to about $\mathrm{LL}=40 \mathrm{~mA}$, and the minimum gain is obtained at $\mathrm{LL}=95 \mathrm{~mA}$. In addition to this operation mode, the $\mathrm{V}_{\mathrm{G}}$ voltage can be maintained constant thus fixing the gain values ( $R x, T x$ ) independently of the line conditions.
For this purpose the $V_{D D}$ voltage, available for supplying the MF generator, can be used.

Figure 8.

b) When gains have to be related to the voltage at the line terminals of the telephone set, it is necessary to obtain $\mathrm{V}_{\mathrm{G}}$ from a resistive divider directly connected to the end of the line.
This type of operation meets for instance the requirements of the French standard. (see the application circuit of fig. 12).

## 4. TRANSDUCERS INTERFACING

The microphone amplifier (3) has a differential input stage with high impedance ( $\cong 40 \mathrm{~K} \Omega$ ) so allowing a good matching to the microphone by means of external resistor without affecting the sending gain. The receiving output stage (6) is particularly intended to drive dynamic capsules. (Low output impedance, $100 \Omega$ max ; high current capability, 3 mAp ).
When a piezoceramic capsule is used, it is useful to increase the receiving gain by increasing R1 value (see the relationship for $\mathrm{V}_{\mathrm{R}}$ ).
With very low impedance transducer, DC decoupling by an external capacitor must be provided to prevent a large DC current flow across the transducer itself due to the receiving output stage offset.

## 5. MULTIFREQUENCY INTERFACING

The LS356 acts as a linear interface for the Multifrequency synthesizer M761 according to a logical signal (mute function) present on pin 3.

When no key of the keyboard is pressed the mute state is low and the LS356 feeds the M761 through pin 15 with low voltage and low current (standby operation of the M761). The oscillator of the M761 is not operating.
When one key is pressed, the M761 sends a "high state" mute condition to the LS356. A voltage comparator (8) of LS356 drives internal electronic switches : the voltage and the current delivered by the voltage supply (9) are increased to allow the operation of the oscillator.
This extra current is diverted by the receiving and sending section of the LS356 and during this operation the receiving output stage is partially inhibited and the input stages of sending and receiving amplifiers are switched OFF.
A controlled amount of the signalling is allowed to reach the earphone to give a feedback to the subscriber ; the MF amplifier (10) delivers the dial tones to the sending paths.
The application circuit shown in fig. 9 fulfils the EUROPE II standard ( $-6,-8 \mathrm{dBm}$ ). If the EUROPE I levels are required $(-9,-11 \mathrm{dBm})$ an external divider must be used (fig. 10).
The mute function can be used also when a temporary inhibition of the output signal is requested.

Figure 12 : Application Circuit without Multifrequency.

Figure 13 : Application Circuit with Gain Controlled by Line Voltage (French standard).

Figure 14 : Application Circuit with Fixed Gain Operation.

In addition to the above mentioned applications, different values for the external components can be used in order to satisfy different requirements.

Figure 15 : External Mute Function.

The following table (refer to the application circuit of fig. 9) can help the designers.

## APPLICATION INFORMATION

| Component | Value. | Purpose | Note |
| :---: | :---: | :---: | :---: |
| R1 | 39.2 ת. | Bridge Resistors | R1 controls the receiving gain. When high current values are allowed, R1 must be able to dissipate up to 1 W . <br> The Ratio R2/R1 fixes the amount of signal delivered to the line. R1 helps in fixing the DC characteristic (see R3 note). |
| R2 | $392 \Omega$ |  |  |
| R3 | $33 \Omega$ | Line Current Sensing. Fixing DC Characteristic | The relationships involving R3 are: $\begin{aligned} & -Z_{M L}=(20 R 3 / / Z B)+R 1 \\ & -G_{s}=K \cdot \frac{Z_{L} / / Z_{M L}}{R 3} \\ & -V_{L}=\left(I_{L}-I_{0}\right)(R 3+R 1)+V_{O} ; V_{0}=3.8 \mathrm{~V} . \end{aligned}$ <br> Without any problem it is possible to have a $Z_{M L}$ ranging from 600 up to $900 \Omega$. As far as the power dissipation is concerned, see R1 note. |
| R4 | $13 \mathrm{~K} \Omega$ | Bias Resistor | The suggested value assures the minimum operating current. It is possible to increase the supply current by decreasing R4 (they are inversely proportional), in order to achieve the shifting of the AGC starting point. |
| R5 | $2.2 \mathrm{~K} \Omega$ | Balance Network | It it possible to change R5 and R6 values in order to improve the matching to different lines ; in any case: |
| R6 | $10 \mathrm{~K} \Omega$ |  | $\begin{aligned} & \frac{Z_{B}}{Z_{L}}=\frac{R 2}{R 1} \\ & Z_{B}=R 5+R 6 / / X_{C 4} \end{aligned}$ |

## APPLICATION INFORMATION (continued)

| Component | Value | Purpose | Note |
| :---: | :---: | :---: | :---: |
| R7-R7' | $100 \Omega$ | Receiver Impedance Matching | R7 and R7' must be equal ; the suggested value is good for matching to dynamic capsule ; there is no problem in increasing and decreasing (down to $0 \Omega$ ) this value. A DC decoupling must be inserted when low resistance levels are used to stop the current due to the receiver output offset voltage (max 200 mV ). |
| R8 | $200 \Omega$ | Microphone Impedance Matching | The suggested value is typical for a dynamic microphone, but it is possible to choose R8 in a wide range. |
| C1 | $10 \mu \mathrm{~F}$ | Regulator AC Bypass | A value greater than $10 \mu \mathrm{~F}$ gives a system start time to high for low current line during MF operation ; a lower value gives an alteration of the $A C$ line impedance at low frequency. |
| C2 | 47 nF | Matching to a Capacitive Line | C2 changes with the characteristics of the transmission line. |
| C3 | 82 nF | Receiving Gain Flatness | C3 depends on balancing and line impedance versus frequency. |
| C4 | 10 nF | Balance Network | See note for R5, R6. |
| C5 | $0.33 \mu \mathrm{~F}$ | DC Filtering | The C5 range is from $0.1 \mu \mathrm{~F}$ to $0.47 \mu \mathrm{~F}$. The lowest value is ripple limited, the higher value is starting up time limited. |
| C6-C7 | 1000 pF | RF Bypass |  |
| C8 | $10 \mu \mathrm{~F}$ | Receiving Output DC Decoupling | See note for R7, R7'. |
| C9 | $1 \mu \mathrm{~F}$ | Receiving Input DC Decoupling |  |

## PROGRAMMABLE TELEPHONE SPEECH CIRCUIT

## DESCRIPTION

The LS588 is a monolithic integrated circuit in 16 lead dual in-line plastic package. Designed as a replacement for the hybrid circuit in telephone sets it performs all the functions previously carried out by this circuit.
With the LS588 it is possible to select the operating mode (fixed or variable gain). The device works with both piezoceramic and dynamic transducers and therefore its gain, both in sending and receiving paths, can be present by means of two external resistors. This feature can also be obtained in AGC operating mode, when the device automatically adjusts the Rx/Tx gains to compensate for the line attenuation by sensing the line current.
The LS588 can supply the decoupling FET when working with an electret microphone. Output impedance can be matched to the line independently of transducer impedance.
In addition, the LS588 can be set in power down state, where the device displays a strow decrease of the current consumption (about 8 mA ), still maintains DC and AC impedances to the line (for parallel operation with a DTMF generator).

## CIRCUIT DESCRIPTION

## 1. DC CHARACTERISTIC

In accordance with CCITT recommendations, any device connected to a telephone line must exhibit a proper DC characteristic $\mathrm{V}_{\mathrm{L}}, \mathrm{I}_{\mathrm{L}}$.
The DC characteristics of the LS588 is determined by the shunt regulator (block 2) together with two series resistors $R_{1}$ and $R_{3}$ (see the block diagram). The equivalent circuit is shown in fig. 5.
A fixed amount, $I_{0}$, of the total available current, $I_{L}$, is drained to allow the circuit to operate correctly. The value of $l_{0}$ can be programmed externally by changing the value of the bias resistor connected to pin 12.
The recommended minimum value of $\mathrm{I}_{0}$ is 7.5 mA with $R$ pin $12=26 \mathrm{~K} \Omega$.
The voltage $\mathrm{V}_{0} \cong 3.8 \mathrm{~V}$ of the shunt regulator is independent of the line current.
The shunt regulator (block 2) is controlled by a temperature compensated voltage reference (block 1). Fig. 6 shows a more detailed circuit configuration of the shunt regulator.
The difference $\mathrm{I}_{\mathrm{L}}$-lo flows through the shunt regulator since $\mathrm{l}_{\mathrm{b}}$ is negligible.
$l_{a}$ is an internal constant current generator ; hence $\mathrm{V}_{\mathrm{O}}=\mathrm{V}_{\mathrm{B}}+\mathrm{la} \cdot \mathrm{R}_{\mathrm{a}}=3.8 \mathrm{~V}$.
The $\mathrm{V}_{\mathrm{L}}, \mathrm{I}_{\mathrm{L}}$ characteristic of the device is therefore similar to a pure resistance in series with a battery.
It is important to note that the DC voltage at pin 16 is proportional to the line current $\mathrm{V}_{16}=\mathrm{V}_{15}+$ $V_{B}=\left(I L-I_{0}\right) R_{3}+V_{B}$.

## 2. TWO TO FOUR WIRES CONVERSION

The LS588 performs the two wire (line) to four wire (microphone, earphone) conversion by means of a Wheatstone bridge configuration thus obtaining the proper decoupling between sending and receiving signals (see fig. 7).
For a perfect balancing of the bridge $\frac{Z_{L}}{Z_{B}}=\frac{R_{1}}{R_{2}}$

The AC signal from the microphone is sent to one diagonal of the bridge (pin 8 and 14). A small percentage of the signal power is lost on $\mathrm{Z}_{\mathrm{B}}$ (since $Z_{B} \gg Z_{L}$ ) ; the main part is sent to the line via $R_{1}$. In receiving mode, the AC signal coming from the line is sensed across the second diagonal of the bridge (pin 7 and 13). After amplification it is applied to the receiving capsule.
The impedance $Z_{M}$ is simulated by the shunt regulator which also acts as a transconductance amplifier for the transmission signal.
The impedance $Z_{M}$ is defined as $\frac{\Delta V_{(14-8)}}{\Delta l_{(14-8)}}$
From fig. 6, considering $C_{1}$ as a short circuit to the $A C$ signâl, any variation in $V_{14}$ generates a variation as follows :

$$
V_{15}=V_{A}=V_{14} \frac{R_{b}}{R_{a}+R_{b}}
$$

the corresponding current change is :

$$
\Delta l=\frac{\Delta V_{15}}{R_{3}}
$$

Figure 5 : Equivalent DC Load to the Line.

therefore

$$
Z_{M}=\frac{\Delta V_{14}}{\Delta I}=R_{3}\left(1+\frac{R_{a}}{R_{b}}\right)
$$

The total impedance across the line connections (pin 13 and 8 ) is given by

$$
Z_{M L}=R_{1}+Z_{M} / /\left(R_{2}+Z_{B}\right)
$$

By choosing $Z_{M} R_{1}$ and $Z_{B} Z_{M}$

$$
Z_{M L} \cong Z_{M}=R_{3}\left(1+\frac{R_{a}}{R_{\mathrm{b}}}\right)
$$

The amplitude of the signal received across pins 13 and 7 can be changed using different values of $\mathrm{R}_{1}$.
(Of course the relationship $\frac{Z_{1}}{Z_{B}}=\frac{R_{1}}{R_{2}}$ must always be
valid.
The received signal is related to the value of $R_{1}$ according to the approximated relationship :

$$
V_{R}=V_{\mathrm{RI}} 2 \quad \frac{R_{1}}{R_{1}+Z_{M}}
$$

Note that if the value of $R_{1}$ is changed the transmission signal current is not changed, since the microphone amplifier is a transconductance amplifier.

## 3. INPUT AND OUTPUT AMPLIFIERS

The microphone amplifier (4) has a differential input stage with high impedance $(\min 11 \mathrm{~K})$ so allowing a good matching to the microphone by means of an external resistor without affecting the sending gain.
The receiving output stage (8) is intended to drive both piezoceramic and dynamic capsules. It has low output impedance, a maximum voltage swing greater than $2 \mathrm{~V}_{\mathrm{p}}$ and a peak current of 2 mA .
With very low impedance transducers, DC decoupling by an external capacitor must be provided to prevent a large DC current flow across the transducer itself due to the receiving output stage offset.

## 4. GAIN CONTROL

It is possible to set the LS588 gain characteristics by means of one pin (pin 1).
When the pin 1 is grounded, the gains of the sending and receiving amplifiers do not depend on the line current (AGC off). When the pin 1 is connected to pin 15 the LS588 automatically changes the gain to compensate for line attenuation (AGC on).
4.1. AGC OFF :In this conditions, as already mentioned, both the sending and the receiving gain are fixed. Their values are determined, independently for the two paths, by the two external resistors $\mathrm{R}_{7}$ (for $T_{x}$, between pin 4 and ground) and $R_{8}$ (for $R_{x}$, between pin 5 and ground), in a wide range (see fig. 8 and 9).
4.2. AGC ON : Starting from any couple of gain values, fixed by the appropriate values of $R_{7}$ and $R_{8}$,
the LS588 can automatically change the sending and receiving gains depending on the line current. The line current is sensed across $\mathrm{R}_{3}$ (see fig. 7) and transferred to pin 16 by the regulator.

$$
V_{16}=V_{B}+V_{15}=V_{B}+\left(I_{L}-I_{0}\right) \cdot R_{3}
$$

Following comparison with an internal reference (block 1) the voltage at pin 1 is used to modify (block 3 ) the gain of the amplifiers (5) and (7) on both the sending and receiving paths.
The starting point of the automatic level control is obtained at $\mathrm{I}_{\mathrm{L}}=25 \mathrm{~mA}$ when the drain current $\mathrm{I}_{0}=$ 7.5 mA .

The external resistors $\mathrm{R}_{7}$ and $\mathrm{R}_{8}$ fix the maximum value for the gains.
Minimum gain is reached for a line current of about 100 mA when the same drain current $\mathrm{I}_{0}$ of 7.5 mA is used.

## 5. DC SHUNT REGULATOR

The LS588 has built into the chip a DC shunt regulator intended to supply (pin 11) the coupling FET when an electret microphone is used. It delivers 1 mAp current with a voltage of 2 Volts (typ) regardless of the line current.

## 6. MUTE CONDITION AND MUTIFREQUENCY INTERFACING

- A logical control (mute) at pin 6 allows operation in parallel with a proper DTMF generator connectable to the line.
- When pin 6 is set high (more than 1.8 Volt) the mute logic circuit (block 9) switches off both sending and receiving stages (mute switch) and reduces (1) the bias current, to sabe about 10 mA , available for the paralleled DTMF generator.
In this condition the LS588 still shows to the line the specified AC impedance ( 650 to $850 \Omega$ ) not provided by the DTMF generator which acts as a current generator.

## 7: ANTICLIPPING APPLICATION

It is possible to avoid distortion of the sending signal limiting the sending gain with an external control at pin 4 (gain programming).
The maximum level to the line will be :

$$
V_{S}=\frac{0.6 \mathrm{~V}}{\sqrt{2}} \times \frac{R_{A C 1}+R_{A C 2}}{-R_{A C 2}}
$$

The following table can be helpful to the designer when choosing different values for the external components, it refers to the typical application circuit of fig. 10.

## TELEPHONE SPEECH CIRCUIT WITH MULTIFREQUENCY TONE GENERATOR INTERFACE

- PRESENTS THE PROPER DC PATH FOR THE LINE CURRENT, PARTICULAR CARE BEING PAID TO HAVE LOW VOLTAGE DROP
- HANDLES THE VOICE SIGNAL, PERFORMING THE $2 / 4$ WIRES INTERFACE AND CHANGING THE GAIN ON BOTH SENDING AND RECEIVING AMPLIFIERS TO COMPENSATE FOR LINE ATTENUATION BY SENSING EITHER THE LINE CURRENT OR THE LINE VOLTAGE. IN ADDITION, THE LS656 CAN ALSO WORK IN FIXED GAIN MODE
- ACTS AS LINEAR INTERFACE FOR MF, SUPPLYING A STABILIZED VOLTAGE TO THE DIGITAL CHIP AND DELIVERING TO THE LINE THE MF TONES GENERATED BY THE M761

## DESCRIPTION

The LS656 is a monolithic integrated circuit in 16lead plastic package to replace the hybrid circuit in telephone set. It works with the same type of transducers for both transmitter and receiver (typically dynamic capsules). Many of its electrical characte-

ristics can be controlled by means of external components to meet different specifications.
In addition to the speech operation, the LS656 acts as an interface for the MF tone signal (particularly for M761 C/MOS frequency synthesizer).

## CIRCUIT DESCRIPTION

1. DC CHARACTERISTIC

The fig. 5 shows the DC equivalent circuit of the LS656.
A fixed amount $l_{0}$ of the total available current $I_{L}$ is drained for the proper operation of the circuit. The value of $l_{0}$ can be programmed externally by changing the value of the bias resistor connected to pin 4 (see block diagram).
The minimum value of $\mathrm{I}_{0}$ is 7.5 mA .
The voltage $\mathrm{V}_{0}=37 \mathrm{~V}$ of the shunt regulator is independent of the line current.

The shunt regulator (2) is controlled by a temperature compensated voltage reference (1) (see the block diagram).

Fig. 6 shows a more detailed circuit configuration of the shunt regulator.
The difference $\mathrm{l}_{\mathrm{L}}$-lof flows through the shunt regulator being $l_{b}$ negligible. $I_{a}$ is an internal constant current generator; hence $\mathrm{V}_{0}=\mathrm{V}_{\mathrm{B}}+\mathrm{l}_{\mathrm{a}} . \mathrm{R}_{\mathrm{a}}=3.7 \mathrm{~V}$.
The $\mathrm{V}_{\mathrm{L}}, \mathrm{l}_{\mathrm{L}}$ characteristic of the device is therefore similar to a pure resistance in series to a battery.

Figure 5 : Equivalent DC Load to the Line.

Figure 6 : Circuit Configuration of the Shunt Regulator.

It is important to note that the DC voltage at pin 5 is proportional to the line current $\left(\mathrm{V}_{5}=\mathrm{V}_{7}+\mathrm{V}_{\mathrm{B}}=\right.$ ( $\mathrm{IL}-$ 10) $\left.\mathrm{R} 3+\mathrm{V}_{\mathrm{B}}\right)$.

The DC characteristic of the LS656 is shown in fig. 7.

Figure 7 : DC Characteristic.

## 2. TWO TO FOUR WIRES CONVERSION

The LS656 performs the two wires (line) to four wires (microphone, earphone) conversion by means of a Wheatstone bridge configuration so obtaining the proper decoupling between sending and receiving signals (see fig. 8).
For a perfect balancing of the bridge $\frac{\mathrm{ZL}}{\mathrm{ZB}}=\frac{\mathrm{R} 1}{\mathrm{R} 2}$
The AC signal from the microphone is sent to one diagonal of the bridge (pin 6 and 9). A small percentage of the signal power is lost on $\mathrm{Z}_{\mathrm{B}}$ (being $\mathrm{Z}_{\mathrm{B}}$ $\gg \mathrm{Z}_{\mathrm{L}}$ ) ; the main part is sent to the line via R 1 . In receiving mode, the AC signal coming from the line is sensed across the second diagonal of the bridge (pin 11 and 10). After amplification it is applied to the receiving capsule.
The impedance $\mathrm{Z}_{\mathrm{M}}$ is simulated by the shunt regulator that is also intended to work as a transconductance amplifier for the transmission signal.

The impedance $Z_{M}$ is defined as $\frac{\Delta V_{6}-9}{\Delta I_{6}-9}$
From fig. 6 considering C1 as a short circuit for AC signal, any variation $\Delta V_{6}$ generates a variation :

$$
\Delta V_{7}=\Delta V_{A}=\Delta V_{6} \cdot \frac{R_{b}}{R_{\mathrm{a}}+R_{\mathrm{b}}}
$$

The corresponding current is

$$
\Delta \mathrm{I}=\frac{\Delta \mathrm{V}_{7}}{\mathrm{R} 3}
$$

Therefore

$$
\mathrm{Z}_{\mathrm{M}}=\frac{\Delta \mathrm{V}_{6}}{\Delta \mathrm{l}}=\mathrm{R} 3\left(1+\frac{\mathrm{R}_{\mathrm{a}}}{\mathrm{R}_{\mathrm{b}}}\right)
$$

The total impedance across the line connections (pin 11 and 9) is given by

$$
Z_{M L}=R 1+Z_{M} / /\left(R 2+Z_{B}\right)
$$

By choosing $Z_{M} \geq R 1$ and $Z_{B} \geq Z_{M}$

$$
\mathrm{Z}_{\mathrm{ML}} \cong \mathrm{Z}_{\mathrm{M}}=\mathrm{R} 3\left(1+\frac{\mathrm{R}_{\mathrm{a}}}{\mathrm{R}_{\mathrm{b}}}\right)
$$

The received signal amplitude across pin 11 and 10 can be changed using different value of R1 (of course the relationship $\mathrm{Z}_{\mathrm{L}} / \mathrm{Z}_{\mathrm{B}}=\mathrm{R} 1 / \mathrm{R} 2$ must be always valid).
The received signal is related to R1 value according to the approximated relationship :

$$
V_{\mathrm{R}}=2 \mathrm{~V}_{\mathrm{RI}} \frac{\mathrm{R} 1}{\mathrm{R} 1+\mathrm{Z}_{\mathrm{M}}}
$$

Note that by changing the value of R1, the transmission signal current is not changed, being the microphone amplifier a transconductance amplifier.

## 3. AUTOMATIC GAIN CONTROL

The LS656 automatically adjusts the gain of the sending and receiving amplifiers to compensate for line attenuation.
This function is performed by the circuit of fig. 9.
The differential stage is progressively unbalanced by changing $\mathrm{V}_{\mathrm{G}}$ in the range 1 to 2 V ( $\mathrm{V}_{\mathrm{REFG}}$ is an internal reference voltage, temperature compensated).
It changes the current $\mathrm{I}_{\mathrm{G}}$, and this current is used as a control quantity for the variable gain stages (amplifier (4) and (5) in the block diagram). The voltage $\mathrm{V}_{\mathrm{G}}$ can be taken :
a) from the LS656 itself (both in variable and in fixed mode) and.
b) from a resistive divider, directly at the end of the line.
a) In the first case, connecting $\mathrm{V}_{\mathrm{G}}$ (pin 8) to the regulator bypass (pin 5 ) it is possible to obtain a gain characteristic depending on the current.
In fact (see fig. 6)

$$
V_{5}=V_{B}+V_{7} \cong V_{B}=\left(\mathrm{IL}-I_{0}\right) R 3
$$

The starting point of the automatic level control is obtained at $\mathrm{IL}=25 \mathrm{~mA}$ when the drain current $\mathrm{l}_{0}=7.5 \mathrm{~mA}$.
Minimum gain is reached for a line current of about 50 mA for the same drain current $\mathrm{I}_{0}=7.5 \mathrm{~mA}$. When $l_{0}$ is increased by means of the external resistor connected to pin 4, the two above mentioned values of the line current for the starting point and for the minimum gain increase accordingly.
It is also possible to change the starting point without changing $\mathrm{l}_{0}$ by connecting pin 8 to the centre of a resistive divider placed between pin 5 and ground (the total resistance seen by pin 5 must be at least $100 \mathrm{~K} \Omega$ ). In this case, the AGC range increases too; for example using a division $1: 1(50 \mathrm{~K} / 50 \mathrm{~K})$ the AGC starting point shifts to about $\mathrm{I}_{\mathrm{L}}=40 \mathrm{~mA}$, and the minimum gain is obtained at $\mathrm{L}_{\mathrm{L}}=95 \mathrm{~mA}$. In addition to this operation mode, the $\mathrm{V}_{\mathrm{G}}$ voltage can be maintained constant thus fixing the gain value ( Rx , Tx ) independently of the line conditions.

For this purpose the $V_{D D}$ voltage, available for supplying the MF generator, can be used.
b) When gains have to be related to the voltage at the line terminals of the telephone set, it is necessary to obtain $\mathrm{V}_{\mathrm{G}}$ from a resistive divider directly connected to the end of the line.

This type of operation meets the requirements of the French standard. (See the application circuit of fig. 13).

## 4. TRANSDUCER INTERFACING

The microphone amplifier (3) has a differential input stage with high impedance ( $\cong 40 \mathrm{~K} \Omega$ ) so allowing a good matching to the microphone by means of external resistor without affecting the sending gain. The receiving output stage (6) is particularly intended to drive dynamic capsules. (Low output impedance ( $100 \Omega \mathrm{max}$ ) ; high current capability 3 mAp ). When a piezoceramic capsule is used, it is useful to increase the receiving gain by increasing R1 value (see the relationship for $\mathrm{V}_{\mathrm{R}}$ ).
Whit very low impedance transducer, DC decoupling by an external capacitor must be provided to prevent a large DC current flow across the transducer itself due to the receiving output stage offset.

Figure 8 : Two to Four Wires Conversion.

## 5. MULTIFREQUENCY INTERFACING

The LS656 acts as a linear interface for the Multifrequency synthesizer M761 according to a logical signal (mute function) present on pin 3.
When no key of the keyboard is pressed the mute state is low and the LS656 feeds the M761 through pin 15 with low voltage and low current (standby operation of the M761). The oscillator of the M761 is not operating.
When one key is pressed, the M761 sends a "high state" mute condition to the LS656. A voltage comparator (8) of LS656 drives internal electronic switches ; the voltage and the current delivered by the voltage supply (9) are increased to allow the operation of the oscillator.

This extra current is diverted by the receiving and sending section of the LS656 and during this operation the receiving output stage is partially inhibited and the input stages of sending and receiving amplifiers are switched OFF.
A controlled amount of the signalling is allowed to reach the earphone to give a feedback to the subscriber ; the MF amplifier (10) delivers the dial tones to the sending paths.
The mute function can be used also when a temporary inhibition of the output signal is requested. The application circuit shown in fig. 10 fulfils the EUROPE II standard $(-6,-8 \mathrm{dBm})$. If the EUROPE I levels are required ( $-9,-11 \mathrm{dBm}$ ) an external divider must be used (see fig. 11).

Figure 15 : Application Circuit with Fixed Gain Operation.

$\begin{array}{ll}R y=0 & \text { Main gain condition } \\ R x=0 & \text { Main gain condition }\end{array}$

Figure 16 : External Mute Function.

In addition to the above mentioned applications, different values for the external components can be used in order to satisfy different requirements.
The following table (refer to the application circuit of fig. 10) can help the designers.

| Component | Value | Purpose | Note |
| :---: | :---: | :---: | :---: |
| R1 | $30 \Omega$ | Bridge Resistors | R1 controls the receiving gain. When high current values are allowed, R1 must be able to dissipate up to 1 W . The Ratio R2/R1 fixes the amount of signal delivered to the line. R1 helps in fixing the DC characteristics (see R3 note). |
| R2 | $330 \Omega$ |  |  |
| R3 | $30 \Omega$ | Line Current Sensing Fixing DC Characteristic | The relationships involving R3 are : $\begin{aligned} & -Z_{M L}=\left(20 R 3 / / Z_{B}\right)+R 1 \\ & -G_{S}=K \cdot \frac{Z_{L} / / Z_{M L}}{R 3} \\ & -V_{L}=\left(I_{L}-I_{0}\right)(R 3+R 1)+V_{0} ; V_{0}=3.7 \mathrm{~V} \end{aligned}$ <br> Without any problem it is possible to have a $\mathrm{Z}_{\mathrm{ML}}$ ranging from 600 up to $900 \Omega$. As far as the power dissipation is concerned, see R1 note. |
| R4 | $13 \mathrm{k} \Omega$ | Bias Resistor | The suggested value assures the minimum operating current. It is possible to increase the supply current by decreasing R4 (they are inversely proportional), in order to achieve the shifting of the AGC starting point. (see fig. 16). After R4 changement, some variations could be found also in other parameters, i.e. line voltage. |
| R5 | $2.2 \mathrm{k} \Omega$ | Balance Network | It's possible to change R5 and R6 values in order to improve the matching to different lines ; in any case:$\begin{aligned} \frac{\mathrm{Z}_{\mathrm{B}}}{\mathrm{Z}_{\mathrm{L}}}=\frac{\mathrm{R} 2}{\mathrm{R1} 1} \\ \mathrm{Z}_{\mathrm{B}}=\mathrm{R} 5+\mathrm{R} 6 / / \mathrm{X}_{\mathrm{C} 4} \end{aligned}$ |
| R6 | $6.8 \mathrm{k} \Omega$ |  |  |
| R7-R7' | $100 \Omega$ | Receiver Impedance Matching | R7 and R7', must be equal ; the suggested value is good for matching to dynamic capsule ; there is no problem in increasing and decreasing (down to $0 \Omega$ ) this value. A DC decoupling must be inserted when low resistance levels are used to stop the current due to the receiver output offset voltage ( $\max 200 \mathrm{mV}$ ). |
| R8 | $200 \Omega$ | Microphone Impedance Matchin |  |

| Component | Value | Purpose | Note |
| :---: | :---: | :--- | :--- |
| C 1 | $10 \mu \mathrm{~F}$ | Regulator AC <br> byPass | A value greater than $10 \mu \mathrm{~F}$ gives a system start time too high for low <br> current line during MF operation ; a lower value gives an alteration of <br> the AC line impedance at low frequency. |
| C 2 | 47 nF | Matching to a <br> Capacitive <br> Line | C2 changes with the characteristics of the transmission line. <br> $\mathrm{C3}$ |
| 82 nF | Receiving <br> Gain <br> Flatness | C3 depends on balancing and line impedance versus frequency. |  |

- RECEIVE GAIN
- RECEIVE LINEARITY
- SIDETONE.
- LOW VOLTAGE OPERATION

## DESCRIPTION

PBL3726 is a family of mask-programmable speech circuits intended for various telephone applications. The flexibility of these circuits allows use of versions of PBL3726 in all telecom markets, whether it be in an ordinary telephone, a hands-free multi-function phone or even as a trunk interface. The versatility is based on three levels :

- Mask options for special requirements
- Pin options on certain functions
- Step-by-step design possibility on the basic telephone functions making it possible to cut down design time to a minimum. This is done by changing the values of a small number of external components.

ABSOLUTE MAXIMUM RATINGS
Maximum Ratings over Operating Free-air Temperature Range (unless otherwise stated)

| Symbol | Parameter | Test Conditions | Unit |
| :---: | :--- | :---: | :---: |
| $V_{D C}$ | Line Voltage, $t_{p}=2 \mathrm{~s}$ | 22 | V |
| $\mathrm{I}_{\mathrm{DC}}$ | Continuous Operating Line Current $\left(^{\star}\right)$ | 100 | mA |
| $\mathrm{~T}_{\mathrm{j}}$ | Junction Temperature | +150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{amb}}$ | Operating Ambient Temperature | -40 to +70 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{stg}}$ | Storage Temperature | -55 to +150 | ${ }^{\circ} \mathrm{C}$ |

(*) Max current increases linearly up to 130 mA with max operating temperature lowered to $+55^{\circ} \mathrm{C}$.

Figure 1 : Block Diagram and Typical Application.

For recommended operating conditions see specific data sheets for different versions of PBL3726

## FUNCTIONAL DESCRIPTION

The gains of the transmitting and receiving amplifiers are continuously and equally changed with the line length. The gain regulation can be cut off externally, and the gain will then be the maximum gain normally used at long lines.

The outputs of the transmitting and receiving amplifiers have internal limitations as to the output amplitudes.
The circuit includes a temperature independent voltage reference used for regulating the DC line current and for regulating the transmitting and receiving gain. The DC voltage quickly settles to its final value with a minimum of overshoot.

The circuit needs few external components. In a normal practical case there are only 5 external capacitors, one of which is an electrolytic/tantalum filter capacitor. The other capacitors are needed for radio interference suppression, to function in the sidetone balancing network, and to provide low frequency cut-off in each of the transmitting and receiving amplifiers.

The circuit has an excellent return loss characteristic against both purely resistive lines such as $600 \Omega$ and against complex networks such as $900 \Omega$ in parallel with 30 nF .
The microphone input is balanced to provide a good CMRR.
It is possible to add a push-button controlled cut-off of the transmitting amplifier of the circuit without disturbing any of the other circuit functions.
A mute input is included to :

1) Cut off the transmitting amplifier ( $F_{1}$ )
2) Reduce gain in the receiving amplifier
3) Reduce current consumption to lower power loss

The DC regulation works independently of the mute function and is not influenced by the mute signal. External mute-control of the circuit from a DTMF generator is then possible.
The receiver amplifier is equipped with a high impedance input stage, allowing a less expensive RC network on the input.

Only resistive elements are used to set the receiving gain.
A push-pull power stage in the receiving amplifier provides a high output swing.
The sidetone balance can be set by an RC network without influencing other parameters. An inexpensive solution requires only one capacitor whereas more capacitors may provide better performance. The sidetone can be regulated with respect to line length.

A separate amplifier stage ( $\mathrm{F}_{3}$ ) can be used in several different ways, for instance.

1) Separating the sidetone balance network
2) Compensating sidetone level for line length
3) Providing an extra 20dB gain for volume control of the receiving amplifier, etc.
This amplifier has many uses. In the following part only two examples of its use are given.

Figure 2.

$A, B, C$ and $D$ are RC links with the following functions:
A: To set the gain and frequency response for transmitting
$B$ : To set the sidetone level (regulation with line length is possible)

C : To set the gain and frequency response for receiving
D : For radio interference suppression and to give the correct return loss behaviour

Figure 3.

In this case an extra 20 dB amplification is added to the receiving part. A potentiometer provides the
possibility of adjusting the gain to the required level.

## BASIC EXTERNAL COMPONENTS

R1, R2.
These resistors set the starting point for the gain and sidetone regulation.
Input impedance on the regulator is about $52 \mathrm{~K} \Omega \pm$ $2 \%$. Only universal versions of PBL 3726 like PBL3726/6, 3726/9 etc. are equipped with this option. In the data sheets for these versions there is a table showing the R1, R2 values for different central office power supplies. The regulation can also be cut off by leaving R1 open and shorting R2 to-LINE voltage.
For other PBL 3726 versions the regulation is set internally for a specific power supply type.

C1, C2, R3.
C1 in series with R3 and these in parallel with C2 determine the impedance to the line from the set.
C2 is normally inserted for radio interference suppression.

The network is optimized with regard to the return loss.
The R3, C1 combination forms a low-pass filter in the DC-feedback loop of the transmitting amplifier. If the R3 C1 time constant is too low there may be distortion at low frequencies.
If R3 is changed this will change the DC characteristics too which is set by the voltage at VDD. The input current at $V_{D D}$ is about 1 mA .

## R4, R5, C3, C4.

The network gives the amplification and frequency response for the transmitter. R5 is used when a greater reduction of the gain is wanted. Input impedance at $F_{2}$ is about $17 \mathrm{~K} \Omega$ with typical variation $\pm 20 \%$. The DC load on $F_{1}$ must be greater than 40K $\Omega$.

Figure 4 : The PBL3726 and External RC Networks.

Figure 5 : Typical Filters.

|  |  |
| :---: | :---: |

R6.
Sets the DC Characteristics and dissipates some of the supplied power. The resistor also affects, the transmitter gain, the output amplitude from the transmitter, the gain regulation and the sidetone. Common values are $68 \Omega$ to $82 \Omega$.

Figure 6 : Typical DC Characteristics.

R7, R8, R9, R10, R11, C5.
This network sets the sidetone balance. The network in the application is one of many possibilities.

R10 an R11 together balance the signals that exit two different ways from the transmitter output stage, one from pin 1 and the other from pin 2. The balance network consists of R8, R9 and C5.
Examples given in the data sheets for different versions of PBL3726 are not optimized to any specified line : they are given only to show the principle.
Amplifier $F_{3}$ has a high input impedance.
Shown in fig. 7 are some different sidetone networks.
Construction of a sidetone network with regulation according to the above can be done as follows:
The balance impedance $A$ is optimized at a short line where the regulation starts. The balance impedance $B$ is optimized at a long line where the regulation stops. The circuit generates a continuous change between the two balance impedances. Rx insures that no DC voltage shall be between F3's double positive inputs at the change.
By breaking up between the negative input and output of $F_{3}$ it can be used as an amplifier with amplification greater than unit. In fig. 8 two balance networks without $F_{3}$ are shown. $\mathrm{F}_{3}$ can then be used in other applications.

Figure 7 : Sidetone Network.

In fig. 9 a circuit is shown, where $F_{3}$ is used as an amplifier with an extra 20 dB gain at receiving and with a volume control.

R12, R13, C6 (R10, R11).
The network gives the gain and frequency response for the receiver.
R13 is used when a greater reduction of the gain is wanted. Input impedance $\mathrm{F}_{4}$ is about $35 \mathrm{~K} \Omega$ with typical variation $\pm 20 \%$. For different possibilities for the design of the network, see the network for the transmitter (R4, R5, C3) in fig. 5.
R14.
Generates the output impedance to the magnetic earphone.
If a dynamic earphone is used it should be placed between outer connections. The middle connection is then not used.

This will give about a double output (for the same output current).
Rectifier. Rectifier bridge and over-voltage protector. The zener voltage at fig. 10 should be as low as possible. Common values are between 12 V and 16V.

Figure 9 : 20dB Extra Amplifier (cannot be used in all version).

Figure 8 : Sidetone Netrwork without F3.

Figure 10 : Rectifier Bridge and Overvoltage Protection.

## DESIGN RULES

The following order should always be used when designing telephone parameters.

1) The circuit impedance to the line
2) DC characteristics
3) Gain regulation
4) Transmitter gain and frequency response
5) Receiver gain and frequency response
6) Sidetone

Components usually have to be added to surpress radio interference, especially from the wires up to the handset.
(The circuit can be placed either in the telephone or in the handset).

## IMPEDANCE.

This is determined with the components $\mathrm{C} 1, \mathrm{C} 2$, and R3 in most cases. In fig. 11 a few examples of this are shown. If a more complex impedance is desired
Figure 11 : Typical Return Loss Against $600 \Omega$.

as in the example for British Telecom (fig. 12), this can also be achieved by copying the mathematical model of the desired impedance.
Examples of line impedance matching :

| Impedance | R3 | C1 | C2 |
| :--- | :---: | :---: | :---: |
| $600 \Omega$ | $600 \Omega$ | $47 \mu \mathrm{~F}$ | 15 nF |
| $900 \Omega, 30 \mathrm{nF}$ | $900 \Omega$ | $47 \mu \mathrm{~F}$ | 15 nF |
| $1.2 \mathrm{k} \Omega, 60 \mathrm{nF}$ | $1.2 \mathrm{k} \Omega$ | $47 \mu \mathrm{~F}$ | 47 nF |

Figure 12 : Example of complex Impedance Matching.

DC CHARACTERISTICS.
The slope of the DC characteristics is set by the resistor R6 (fig. 13). The lower value of R6, the flatter the slope. With the steaper slope the minimum DC
Figure 13 : Typical DC Characteristics.

voltage also will go down. It is not recommended, though, to set the PBL3726 to DC voltages below 2.5 V . If in some circumstances the DC characteristics of PBL3726 is too low, they can be raised by inserting an extra diode in series with the rectifier bridge as in fig. 14.

## GAIN REGULATION.

When regulation with line length is used on send and receive gain, this can be set with the resistors R1 and R2. Note that not all versions are equipped with this function. By changing the values of these, the regulation attack can be set to fit any particular need.

Figure 14 : Rectifier Bridge with Extra Diode.

A table in the data sheets shows what values to use for some standard power supply systems. See example in fig. 15.
Figure 15 : Examples of Line-regulation Setting.

| Line | R1 | R2 |
| :--- | :---: | :---: |
| $50 \mathrm{~V}, 2 \times 200 \Omega$ | $18 \mathrm{k} \Omega$ | $47 \mathrm{k} \Omega$ |
| $50 \mathrm{v}, 2 \times 400 \Omega$ | $9.1 \mathrm{k} \Omega$ | $47 \mathrm{k} \Omega$ |
| $50 \mathrm{~V}, 2 \times 800 \Omega$ | 0 | $\infty$ |
| Unregulated (all lines) | $\infty$ | 0 |

Regulation input (pin 6 on PBL3726/6)

Figure 16 : Typical Gain Regulation with Line Lenght.

## TRANSMITTER GAIN.

The resistor R 4 sets the gain by attenuating the signal from amplifier $\mathrm{F}_{1}$. If greater attenuation is needed a resistor (R5) can be connected to the minus line.
To get a frequency response appropriate for the microphone used a filter function as in fig. 5 can be used. These filters were previously described in this document.

The circuit can be provided with an unbalanced input as in fig. 18.
Cuit off of the transmitter can be done at $F_{1}$ without interfering other functions of the circuit as in fig. 19. Also signals other than DTMF signals can be added at input of $\mathrm{F}_{2}$.
Figure 17 : Typical Response of PBL3726 Using Simple Filter.

For the version originally developed for electrodynamic/magnetic microphones it is also possible to use electret microphones as shown in fig. 20.

## RECEIVER GAIN

In order to get the correct gain on the receive side, resistors R10-R13 are used. Remember that R10 and R11 also set the rough ratio of the sidetone. R13 is used only in extreme circumstances, where a very
Figure 18 : Unbalanced Input.

Figure 19 : Special Function.

Figure 20 : Alternative Microphones of Electromagnetic and Electrodynamic Types for PBL3726.

high receive gain attenuation is needed. The frequency response can be altered with the same filters used for the send gain (see fig. 5). To get protection against acoustic shock the diodes provided on some versions after the output of $\mathrm{F}_{4}$ can be used.
One or two diode pairs can be used. Should this not be enough a resistor can be connected after the diodes (in series). This should be done before the setting of the receive gain.

Figure 21 : Typical Receive Gain.

SIDETONE

$$
S T M R=-\frac{10}{m} \times 10_{\log }^{\substack{\sum 10 \\ i=1}}\left\{\frac{m}{10}\left(W_{S T}+L_{E} S_{S}+S_{R}+A_{\text {rst }}\right)\right\}
$$

The most difficult part of the design work is always to define the sidetone. This should always be done last when designing with PBL3726. The sidetone is the sound of your own voice fed back into the ear by the handset.

The subjective effect of this is best seen in the formula above for "Side Tone Masking Rating".
Summed at the frequencies $\mathrm{f}_{\mathrm{I}}=0.2$,
0.25 . $\qquad$ . 4 KHz (see fig. 22)
$\mathrm{W}_{\text {ST }}=$ Weighing factor
$L_{E}=$ Leakage at receiver capsule
Ss = Send sensitivity
$S_{R}=$ Receive sensitivity
Arst $=$ Hybrid-loss balance
The part that can be alteren by the speech circuit is the Arst value that can be determined by the formula:

$$
A_{\text {rst }}=2010_{\log }\left[\frac{Z_{c}+Z_{s o}}{2 Z_{c}} \times \frac{Z+Z_{c}}{Z-Z_{s o}}\right]
$$

Where :
$\mathrm{Z}=$ Impedance of the connected telephone line
$Z_{s o}=$ The balance impedance of the central office (PABX)
$\mathrm{Z}_{\mathrm{C}}=$ Impedance of the speech circuit
The sum of $Z$ and $Z_{\text {so }}$ can be called $Z_{\text {line }}$
The principle of the traditional so called active speech circuit has been the wheatstone bridge (fig. 23). The formula for the minimum sidetone is to balance until :

$$
\frac{Z_{2}}{Z_{1}}=\frac{Z_{\text {bal }}}{Z_{\text {line }}}
$$

Figure 22 : CCITT Factors.

| $\mathbf{f}_{1}$ <br> $\mathbf{k H z}$ | $\mathbf{W}_{\mathbf{S T}}$ <br> $\mathbf{d B}$ | $\mathbf{L}_{\mathbf{E}}$ <br> $\mathbf{d B}$ |
| :---: | :---: | :---: |
| 0.2 | 86.4 | 8.4 |
| 0.25 | 81.9 | 4.9 |
| 0.315 | 78.5 | 1 |
| 0.4 | 78.2 | -0.7 |
| 0.5 | 72.8 | -2.2 |
| 0.63 | 67.6 | -2.6 |
| 0.8 | 58.4 | -3.2 |
| 1 | 49.7 | -2.3 |
| 1.25 | 48.0 | -1.2 |
| 1.6 | 48.7 | -0.1 |
| 2 | 50.7 | 3.6 |
| 2.5 | 49.8 | 7.4 |
| 3.15 | 48.4 | 6.7 |
| 4 | 49.2 | 8.8 |

The principle of PBL3726 is more complicated (even if calculation with the bridge in fig. 23 is possible). With the all-active bridge a method of cancelling the sidetone is a summing amplifier makes it possible to get not only one but two different sidetone optimums for different line lengths (see fig. 25). The function of the external components in fig. 7 have previously been described in this document. Fig. 26 shows an example of a sidetone network using the Wheatstone principle with PBL3726.

## APPLICATIONS

To use PBL3726 in a hands-free telephone with a monitor function the schematics in fig. 27 can be used. The transformer should be rather efficient. Ordinary transistors can be used.
PBL3726 can also be used as trunk interface in modems, PABX, key systems etc where an analog
interface against the telephone line is needed. The balanced inputs and outputs make this possible together with the possibility of regulated sidetone. Examples of both one-way and two-way data/signal communication with PBL3726/6 are shown in fig. 28.

Figure 27 : Monitor Loudspeaker.

TWO - WAY COMMUNICATION (SEND/RECEIVE)

## MASK - PROGRAMMABLE SPEECH CIRCUITS

## SPEECH CIRCUIT

- MINIMUM NUMBER OF INEXPENSIVE EXTERNAL COMPONENTS, 5 CAPACITORS AND 10 RESISTORS
- MUTE FUNCTION FOR PARALLEL OPERATING WITH DTMF GENERATOR OR DECADING IMPULSING
- LOW VOLTAGE OPERATING, DOWN TO 3.3V
- VERY SHORT START-UP TIME

## DESCRIPTON

PBL3726/6 is standard version of the PBL3726 family of the mask-programmable, monolithic integrated speech circuits for use with a low impedance microphone. Sending and receiving gain is regulated with line length. Different ranges of amplifier regulation for various current feeds can be obtained with external resistor or totally cut off. Typical current feeds as $48 \mathrm{~V} 2 \times 200 \Omega 2 \times 400 \Omega$ and 36 V $2 \times 250 \Omega$ can be handled.

Application-dependent paremeters as line balance, sidetone level and frequency response are set by external components. Parameters are set independently which means easy adaptation for various market needs. An extra 20dB amplifier can be used for various purposes such as extra receiving gain with volume control or active sidetone balance.

## MASK - PROGRAMMABLE SPEECH CIRCUITS

## SPEECH CIRCUIT

- MINIMUM NUMBER OF INEXPENSIVE EXTERNAL COMPONENTS, 6 CAPACITORS AND 10 RESISTORS
- MUTE FUNCTION FOR PARALLEL OPERATION WITH DTMF GENERATOR OR DECADING IMPULSING
- LOW VOLTAGE OPERATION, DOWN TO 3.3V
- VERY SHORT START-UP TIME
- CURRENT-SOURCE GENERATOR FOR ACTIVE MICROPHONES

## DESCRIPTON

PBL3726/8 is a standard version of the PBL3726 family of the mask-programmable, monolithic integrated speech circuits for use in electronic telephones. It is designed for use with a low impedance microphone. Sending and receiving gain is regulated with the line length. Different ranges of amplifier regulation for various current feeds can be obtained by mask programming. Typical current feeds such as $48 \mathrm{~V} 2 \times 800$, and $36 \mathrm{~V} 2 \times 500$ can be handled.

## TEST CIRCUIT

Application-dependent parameters are line balance, sidetone level and frequency response are set by external components. Parameters are set independently which means easy adaptation for various market needs. An extra 20dB amplifier can be used for various purposes such as extra receiving gain with volume control or active sidetone balance.

Figure 1 : Typical Application.

Some typical values for R1 and R2 for some different supplies from telephone stations are shown in the next table.

| Type | R1 | R2 |
| :--- | :---: | :---: |
| No Regulation, all Feeding <br> Systems | $\infty$ | 0 |
| $48 \mathrm{~V}, 2 \times 200 \Omega$ | $16 \mathrm{~K} \Omega$ | $47 \mathrm{~K} \Omega$ |
| $48 \mathrm{~V}, 2 \times 400 \Omega$ | 9.1 K | $47 \mathrm{~K} \Omega$ |

## MASK - PROGRAMMABLE SPEECH CIRCUITS

## SPEECH CIRCUIT

- MINIMUM NUMBER OF INEXPENSIVE EXTERNAL COMPONENTS, 5 CAPACITORS AND 10 RESISTORS
- MUTE FUNCTION FOR PARALLEL OPERATION WITH DTMF GENERATOR OR DECADING IMPULSING
- LOW VOLTAGE OPERATION, DOWN TO 3.3 V
- VERY SHORT START-UP TIME
- SEPARATE POWER SUPPLY POSSIBLE FOR OUTPUT AMPLIFIER

## DESCRIPTON

PBL3726/12 is a standard version of the PBL3726 family of the mask-programmable, monolithic integrated speech circuits for use in electronic telephones. It is designed for use with a low impedance microphone. Sending and receiving gain is regulated with line length. Different ranges of amplifier regulation for various current feeds can be obtained. Typical current feeds as $48 \mathrm{~V} 2 \times 250 \Omega 2 \times 400 \Omega$ and $36 \mathrm{~V} 2 \times 250 \Omega$ can be handled.

Application-dependent parameters such as line balance, sidetone level and frequency response are set by external components. Parameters are set independently which means easy adaptation for various market needs. An extra 20 dB amplifier can be used for various purposes such as extra receiving gain with volume control or active sidetone balance.

## TEST CIRCUIT

## ABSOLUTE MAXIMUM RATINGS

(Maximum Ratings over Operating Free-air Temperature Range unless otherwise stated)

| Symbol | Parameter | Test Conditions | Unit |
| :---: | :--- | :---: | :---: |
| $V_{D C}$ | Line Voltage, $t_{p}=2 \mathrm{~s}$ | 22 | V |
| $\mathrm{I}_{\mathrm{DC}}\left({ }^{*}\right)$ | Continuous Operating Line Current | 100 | mA |
| $\mathrm{~T}_{\mathrm{j}}$ | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {amb }}$ | Operating Ambient Temperature | -40 to +70 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{stg}}$ | Storage Temperature | $-55 \mathrm{to}+150$ | ${ }^{\circ} \mathrm{C}$ |

(*) Max. current increases linearly up to 130 mA with max operating temperature lowered to $+55^{\circ} \mathrm{C}$.

RECOMMENDED OPERATING CONDITIONS

## SPEECH AND TONE CIRCUIT

- AUTOMATIC LINE LENGTH RECEIVING AND SENDING GAIN CONTROL
- AUTOMATIC LINE LENGTH TRACKING ANTISIDETONE SYSTEM
- ADJUSTABLE MICROPHONE AND EARPHONE AMPLIFIER GAIN
- MEETS FRENCH VOLTAGE/CURRENT LIMITATIONS IN SPEECH AND RING MODE
- ADAPTED TO EVERY KIND OF EARPHONE TRANSDUCER
- MUTE IN EMISSION AND RECEPTION
- PABX POSITION
- TWO KEYS ROLL OVER PROVIDED
- ADJUSTABLE OUTPUT TONE LEVEL
- CLICK FREE SWITCH OVER FROM SPEECH TÓ DIALING MODE \& VICE-VERSA

## DESCRIPTION

Specially designed for telephone set applications this 28 pins IC provides:
a) Transmission and line adaptation
b) F.V. generation
c) Power supply for peripherals
d) Interface with MCU

It meets the French Specifications for handset homologation level 1.

## PUBLIC / PRIVATE

When a resistor is inserted between pin 10 and ground, the transmission and receiving efficiency control and antisidetone variation are inhibited with respect to line current.
The transmission and receiving gains may vary from
$\mathrm{G}_{\max }(\mathrm{gel})$ to $\mathrm{G}_{\max } 6 \mathrm{~dB}(\mathrm{Gec})$ with respect to the resistance value.
The equivalent antisidetone is related to the gain set by Rlp

Figure 1 : Transmission and Receiving Gain Attenuation.

## TEST CIRCUIT

## CIRCUIT DESCRIPTION

1. DC-CHARACTERISTICS
1.1. VC (PIN 25). The stabilized voltage Vc is connected to Vline (pin 24) through an internal shunt regulator which presents to the line a high AC.impe-
dance at frequencies higher than 200 Hz . At this purpose the value of C1 (at pin 25) must be not lower than 47 microFarad.

Figure 1.

At "Off-hook", with only DC voltage applied to the line terminals, C 1 fixes the timing of the line current profile at :

- 150 mA max for a time shorter than 400 msec (T-charge)
- 60 mA max in steady state (conversation)

Figure 2.

1.2. HOOK DETECTION (in ring mode) (pin 19). The DC-characteristic requested to allow off-hook detection by the exchange during ring call may be accomplished:
a) through an analog control (R-C) or
b) by a microprocessor.
a) Application with standard dialer (analog control) The components R1, R2 and C2 define the timing
of the DC characteristic and also limit at 75 mA -peak the line current during decadic dialing.
Optimum values are : - R1 x C2 = 1.8sec ; $\mathrm{R} 2 \times \mathrm{C} 2=0.8 \mathrm{sec}$.
To reduce the minimum time between a "on-hook/ off-hook" sequence, R2 may be replaced by a switch to ground.

Figure 3.

b) Application with a microprocessor

Pin 19 may be controlled directly by the micro-controller, through a resistor R1b which replaces R1, R2 and C2.
Figure 4.

1.3. VLINE (PIN 24). The line voltage (pin 24) is determined by the value of the external resistor R6 and by the internal current, lint, flowing between Vc (pin 25) and Ground (see also paragr. 1.1.) :

$$
\text { Vline }=\mathrm{Vc}+\mathrm{R} 6 \times \text { lint. }
$$

Vc is fixed by design at about 2.8 volts.
lint is reversely related to R9 (lint $=12 \mathrm{~V} /$ R9 at lline $=27 \mathrm{~mA}$ ).

Figure 5.

Vline must be externally adjusted (with R6) to guarantee both DC and AC characteristic in accordance to the french standards. At this purpose it is suggested that Vline equals 5.6 volts at lline $=16 \mathrm{~mA}$. This typical value is obtained with $\mathrm{R} 6=7.5 \mathrm{Kohm}$.
1.4. HIGH VOLTAGE CONTROL STAGE (PIN 21). The behaviour of "HV control" is determined by several conditions, both internal (lline sensor) and external (pins 19 and 25) with the purpose to accomplish the different DC characteristics and transitory conditions imposed by the French specification :
a) steady DC-characteristic and lightnings (pins 19 and 25 ON )
b) DC-characteristic at off-hook (pin 19 and 25 grounded)
c) DC-characteristic during decadic dialing (pin 25 grounded)
d) DC-characteristic after off-hook in ringing (pin 19 grounded)
To do that, HV control pin regulates the current injected into the external high voltage transistor stage, requested by the French specification.

Figure 6.

b) pin 19 and 25 grounded

c) pin 19 ON ; PIN 25 grounded

d) pin 19 grounded ; pin 25 ON

## Figure 7.

2.1. A.G.C. IN TRANSMISSION. The transmission gain between Microphone Input (pin 8) and Vline (pin 24) is internally decreased of 6 dB when the line current varies from 27 mA to 42 mA with a constant AC load of 600 ohms.
2.2. SENDING IMPEDANCE. The impedance of the Output Stage Amplifier, Zout, is determined by the impedance $\mathrm{Z4}$ at pin 3.

$$
\text { Zout }=10.65 \times \text { Z4. }
$$

The total AC impedance shown to the line is the parallel
Zpar = Zout/Zint/Zext
where:

- Zint $=10$ kohm $/ / 8.5 n F$ (internal)
- Zext = R6 // C4 (at pin 24)
2.3. SENDING MUTE. In normal speech operation (Vmute 0.8 V ), the signal at Microphone Input (pin 8) is amplified to Vline (pin 24) with the gains Gec (short line), Gel (long line) or intermediate, depending on lline.
In sending mute condition (Vmute 1.6 V ) these gains are reduced of at least 60 dB . In the same condition DTMF input (pin 7) is activated, with gain Gmf to the line independent from lline.
2.4. ANTISIDETONE BUFFER. The signal coming from the sending preamplifier is internally presented
at pin 5 and than buffered to pins 1 and 2 for sidetone cancellation (see paragraph 3.2.).
2.5. NOISE THRESHOLD (SQUELCH). The microphone signal is highly amplified ( 46 dB ) at pin 16 , then peak detected and compared with an internal threshold at pin 14.
If the peak so detected does not exceed the internal threshold, the comparator reduces of about 9 dB the sending gain Ge , acting at the preamplifier level.
In this way a strong attenuation is obtained, both of the speech noise (about 4 dB ) and of the ambient noise (9dB).
The equivalent thresholds on the line are :
- minus 39 dBm to switch from squelch to normal gain,
- minus 32 dBm to switch from normal gain to squelch,
with $R 8=150 \mathrm{~K} \Omega$ from pin 15 to gnd and $\mathrm{C}=3.3 \mathrm{nF}$ from pin 16 to 15.
These thresholds can be increased inserting also a resistor (R7) in series to C between pin 16 and 15.
The variation is given by the formula : ( $R 8+R 7$ )/R8.
A hysteresis of about 3 dB is defined to avoid continuous switch between squelch and normal gain.

Figure 8.

## 3. RECEIVE CHAIN

Figure 9.

3.1. A.G.C. IN RECEIVE. As described for the transmission chain, also the receiving gains Gr , from pins 1 and 2 to pin 28, have a reduction of 6 dB when lline moves from 27 mA to 42 mA .
3.2. SIDETONE COMPENSATION. The circuit is provided with a double anti-sidetone network to optimize sidetone both at long and short lines.
Before entering pins 1 and 2, the received signal is attenuated by two attenuating networks:

- Zall / Zrl to pin 1 for long lines sidetone compensation,
- Zalc / Zrc to pin 2 for short lines sidetone compensation.
Zrl and Zrc define the total receive gains:
a) $\frac{\mathrm{V} 28}{\mathrm{~V} 24}=\mathrm{Grl} \times \frac{\mathrm{Zrl}}{\mathrm{Zrl}+\mathrm{Zall}}$ for long lines
b) $\frac{\mathrm{V} 28}{\mathrm{~V} 24}=\operatorname{Grc} x \frac{\mathrm{Zrc}}{\mathrm{Zrc}+\text { Zalc }}$ for short lines

Zall and Zalc define the sidetone compensation of the circuit.
The equivalent balancing impedance is given by the formula :

$$
\mathrm{Zal}=\mathrm{K} \times \text { Zalc }+(1 \mathrm{~K}) \times \text { Zall }
$$

where $\mathrm{K}=0$ at lline $=27 \mathrm{~mA}$ or lower (long line)
$K$ varies from 0 to 1 with line between 27 mA
and 42 mA ,
$\mathrm{K}=1$ at lline=42mA or higher (short line).
Calculations to define Zall and Zalc are :
a) Zall $=70 \times$ R5 $\times \frac{\text { Zline(long) // Zext // Zint // Zout }}{\text { Zout }}$
b) Zalc $=70 \times$ R5 $\times \frac{\text { Zline(short) // Zext // Zint // Zout }}{\text { Zout }}$ where:

- Zext = R6 // C4 // (Zelectret) (at pin 24)
- Zint = 10Kohms // 8.5 nF (internal impedance)
- Zout $=10.65 \times$ Z4 (at pin 3 ; see paragr. 2.2.)
- Zline(short) and (long) are the impedances of the line at 0 Km and 3.5 Km .
- R5 = 5.1 Kohm $\pm 1 \%$
3.3. AC IMPEDANCE. The total AC impedance of the circuit to the line is :
Zpar = Zout/Zint/Zext/Zalc//Zall (see par. 2.2. and 3.2.)
= Zout//Zint/Zext (Zalc, Zall Zpar)
3.4. RECEIVE MUTE (and confidence level). When the receive channel is muted (Vpin 182.7 V ) the receive gain is reduced of 60 dB minimum.
In this condition an internal connection is activated from DTMF input (pin 7) to Receive Output (pin 28) with a gain $\mathrm{Gmf}=31 \mathrm{~dB}$ to provide acoustic feedback of the DTMF transmission.

## 4. MICROPROCESSOR INTERFACE

4.1. MICROPROCESSOR SUPPLY (PIN 27). At "offhook" the first priority of the circuit is to make some current available at the Microprocessor Supply (pin 27) to charge quickly the external capacitor C3.
This charging current is: $\mathrm{lcpm}=0.7 \times$ (lline -Idem ), where Idem $=2.6 \mathrm{~mA}$ is the current charging C 1 .
$\mathrm{Vmp}=3.3 \mathrm{~V}$ in normal operation and current increases linearly.from 0.5 mA min , at lline $=6 \mathrm{~mA}_{r}$ to 2.5 mA min, at lline $=27 \mathrm{~mA}$, remaining stable for higher values of lline.

Figure 10.

4.2. MICROPROCESSOR RESET (pin 20). The Microprocessor Reset becomes active when Vmp overcomes $85 \%$ of its nominal level.

It becomes low when Vmp undergoes 84\%.
Slope A is related to C 3 , limp (internal consumption) and to the external load (microprocessor or dialer).

Figure 11.

## 5. PUBLIC / PRIVATE

5.1. A.G.C. OFF (PIN 10). An external resistor, R18, applied between pin 10 and ground disconnects the AGC control.
Sending, receiving gain and sidetone compensation
are now independent of the line length and the value of the current Ip , flowing through R18, defines the length of the line for which sidetone is optimized ( $\mathrm{lp}=2.7 \mathrm{~V} / \mathrm{R} 18$ ).

Figure 12.

5.2. SECRET FUNCTION FOR PRIVATE (PINS 11 \& 18). The two separate Mute pins allow "Secret Function" (only microphone muted).
As the two controls have different threshold levels, they can be operated :
a) separately through two different control logic,
b) connected in short circuit with a three levels logic ( $\mathrm{Vm}=0 \mathrm{~V}$ speech mode ; $\mathrm{Vm}=1.8 \mathrm{~V}$ microph mute ; $\mathrm{Vm}=3 \mathrm{~V}$ all mute).

## 6. POWER MANAGEMEN AND HANDS-FREE INTERFACE

6.1. POWER MANAGEMENT (PIN 12). Most of the DC current available from the line will be delivered by the speech circuit at the output Isource (pin 12) through an internal current generator.
Typical values of this current, lea, are :

- lea $=(0.3 \times$ lline $)$ for lline $<22 \mathrm{~mA}$
- lea $=(0.9 x$ lline 13 mA$)$ for lline $>22 \mathrm{~mA}$
(ex: lline $=16 \mathrm{~mA}$ then lea=4.8mA
lline $=30 \mathrm{~mA}$ then lea $=14.0 \mathrm{~mA}$
lline $=60 \mathrm{~mA}$ then lea $=41.0 \mathrm{~m}$ )

The voltage level at pin 12 must be defined by an external regulator (i.e. : zener) and, if necessary, filtered with a capacitor ( 47 to $220 \mu \mathrm{~F}$ ).
In case Vline (at pin 24) approaches V at pin 12, then the internal current source switches off and its DC current is shunt to ground through an intemal complementary generator, thus avoiding any negative effect on the Ac and DC impedances of the telephone set application.

Figure 13.

6.2. EXTRA RECEIVE OUTPUT (PIN 4). The Extra Receive Signal is active also in Receive Mute condition, so allowing the transit of the receive signal from the speech circuit to the Hands-Free system even when the earpiece is muted.

The gain at this pin is 30 dB lower than standard Receive Output (pin 28).

## SPEECH CIRCUIT WITH POWER MANAGEMENT

ADVANCE DATA

- 2/4 WIRES INTERFACE WITH
- Double antisidetone network
- Rx gain and AC impedance externally programmable
- DTMF INTERFACE
- PULSE DIAL INTERFACE
- 4.0 VOLTS SUPPLY FOR MICROPROCESSOR OR DIALER
- RESET TO MICROPROCESSOR
- CURRENT SUPPLY FOR LOUDSPEAKER
- HANDS-FREE INTERFACE
- DC CHARACTERISTIC AND ON/OFF HOOK FOR FRANCE
- CONTROL AGAINST HIGH VOLTAGE TRANSIENTS

## DESCRIPTION

The TEA7052 is expressely designed to meet the french specification for telephone set in medium and high range equipments.

## TEST CIRCUIT

## CIRCUIT DESCRIPTION

## 1. DC-CHARACTERISTICS

1.1. VC (pin 21). The stabilized voltage Vc is connected to Vline (pin 20) through an internal shunt regulator which presents to the line a high AC impe-
dance at frequencies higher than 200 Hz . At this purpose the value of C 1 (at pin 21) must be not lower than 47 microFarad.

Figure 1.

At "Off-hook", with only DC voltage applied to the T-charge of 240 msec (typ) is obtained with
line terminals, C1 fixes the timing of the line current profile at :

- 150mA max for a time shorter than 400 msec (T-charge)
$\mathrm{C} 1=220 \mu \mathrm{~F}$.
T-charge $=\frac{\text { VcxC1 }}{\text { Idem }}$ typically.
- 60 mA max in steady state (conversation)

Figure 2.

1.2. HOOK DETECTION (in ring mode) (pin 15).

The DC-characteristic requested to allow off-hook detection by the exchange during ring call may be accomplished:
a) through an analog control (R-C) or.
b) by a microprocessor.
a) Application with standard dialer (analog control)
The components R1, R2 and C2 define the timing of the DC characteristic and also limit at 75mA-peak the line current during decadic dialing.

Optimum values are : - R1 x C2 = 1.8 sec ;
R2 $\times$ C2 $=0.8 \mathrm{sec}$.
To reduce the minimum time between a "on-hook / off-hook" séquence, R2 may be replaced by a switch to ground.

Figure 3.

b) Application with a microprocessor

Pin 15 may be controlled directly by the micro-controller, through a resistor R1b which replaces R1, R2 and C2.
Figure 4.

1.3. VLINE (pin 20). The line voltage (pin 20) is determined by the value of the external resistor R6 and by the internal current, lint, flowing between Vc (pin 21) and Ground (see also paragr. 1.1.) :

Vline $=\mathrm{Vc}+\mathrm{R} 6 \times$ lint.

Vc is fixed by design at about 2.6 volts.
Lint is reversely related to R9 (Lint $=7.5 \mathrm{~V} / \mathrm{R} 9$ at lline $=27 \mathrm{~mA}$ ).

Figure 5.

Vline must be externally adjusted (with R6) to guarantee both $D C$ and $A C$ characteristic in accordance to the french standards. At this purpose it is suggested that Vline equals 5.6 volts at lline $=16 \mathrm{~mA}$. This typical value is obtained with $R 6=13 \mathrm{Kohm}$.
1.4. HIGH VOLTAGE CONTROL STAGE (pin 17). The behaviour of "HV control" is determined by several conditions, both internal (lline sensor) and external (pins 15 and 21) with the purpose to accomplish the different DC characteristics and transitory conditions imposed by the French specification :
a) steady DC-characteristic and lightnings (pins 15 and 21 ON)
b) DC-characteristic at off-hook (pin 15 and 21 grounded)
c) DC-characteristic during decadic dialing (pin 21 grounded)
d) DC-characteristic after off-hook in ringing (pin 15 grounded)
To do that, HV control pin regulates the current injected into the external high voltage transistor stage, requested by the French specification.

Figure 6.

b) pin 19 and 25 grounded

c) pin 19 ON ; PIN 25 grounded

d) pin 19 grounded ; pin 25 ON

## 2. TRANSMISSION CHAIN

Figure 7.

2.1. A.G.C. IN TRANSMISSION. The transmission gain between Microphone Input (pin 8) and Vline (pin 20) is internally decreased of 6 dB when the line current varies from 27 mA to 42 mA with a constant AC load of 600 ohms.
2.2. SENDING IMPEDANCE. The impedance of the Output Stage Amplifier, Zout, is determined by the impedance Z4 (at pin 3).

$$
\text { Zout = } 10.65 \times \mathrm{Z4} .
$$

The total $A C$ impedance shown to the line is the parallel
Zpar = Zout/Zint/Zext
where:

- Zint = 10kohm // 8.5ñF (internal)
- Zext = R6 // C4 (at pin 20)
2.3. SENDING MUTE. In normal speech operation (Vmute $<0.8 \mathrm{~V}$ ), the signal at Microphone Input (pin 8) is amplified to Vline (pin 20) with the gains Gec (short line), Gel (long line) or intermediate, depending on lline.
In sending mute condition :'(Vmute $>1.6 \mathrm{~V}$ ) these gains are reduced of at least 60 dB . In the same condition DTMF input (pin 7) is activated, with gain Gmf to the line independent from lline.
2.4. ANTISIDETONE BUFFER. The signal coming from the sending preamplifier is internally presented at pin 5 and than buffered to pins 1 and 2 for sidetone cancellation (see paragraph 3.2.).

## 3. RECEIVE CHAIN

Figure 8.

3.1. A.G.C. IN RECEIVE. As described for the transmission chain, also the receiving gains Gr , from pins 1 and 2 to pin 24, have a reduction of 6 dB when lline moves from 27 mA to 42 mA .
3.2. SIDETONE COMPENSATION. The circuit is provided with a double anti-sidetone network to optimize sidetone both at long and short lines.
Before entering pins 1 and 2 , the received signal is attenuated by two attenuating networks:

- Zall / Zrl to pin 1 for long lines sidetone compensation,
_ Zalc/ Zrc to pin 2 for short lines sidetone compensation.
Zrl and Zrc define the total receive gains :
a) $\frac{\mathrm{V} 24}{\mathrm{~V} 20}=\operatorname{Grl} \times \frac{\mathrm{Zrc}}{\text { Zrl + Zall }} \quad$ for long lines
b) $\frac{V 20}{V 24}=\operatorname{Grc} x \frac{Z r c}{Z r c}+$ Zalc $\quad$ for short lines

Zall and Zalc define the sidetone compensation of the circuit.
The equivalent balancing impedance is given by the formula :
Zal = K x Zalc + (1-K) x Zall
where $K=0$ at lline $=27 \mathrm{~mA}$ or lower (long line) K varies from 0 to 1 with Iline between 27 mA and 42 mA ,
$K=1$ at lline $=42 \mathrm{~mA}$ or higher (short line).
Calculations to define Zall and Zalc are :
a) Zall $=70 \times$

b) Zalc $=70 \times$ R $5 \times \frac{\text { Zline(short) // Zext // Zint // Zout }}{\text { Zout }}$
where:

- Zext = R6 // C4 // (Zelectret) (at pin 20)
- Zint $=10 \mathrm{Kohms} / / 8.5 \mathrm{nF}$ (internal impedance)
- Zout $=10.65 \times$ Z4 (at pin 3 ; see paragr. 2.2.)
- Zline (short) and (long) are the impedances of the line at 0 Km and 3.5 Km .
- $\mathrm{R} 5=5.1 \mathrm{Kohm} \pm 1 \%$
3.3. AC Impedance. The total AC impedance of the circuit to the line is:
Zpar = Zout/Zint/Zext/Zalc//Zall (see par. 2.2. and 3.2.)
= Zout/Zint/Zext (Zalc, Zall Zpar)
3.4. RECEIVE MUTE (and confidence level). When the receive channel is muted (Vpin $14>2.7 \mathrm{~V}$ ) the receive gain is reduced of 60 dB minimum.
In this condition an internal connection is activated from DTMF input (pin 7) to Receive Output (pin 24) with a gain $\mathrm{Gmf}=38.5 \mathrm{~dB}$ to provide acoustic feedback of the DTMF transmission.

## 4. MICROPROCESSOR INTERFACE

4.1. MICROPROCESSOR SUPPLY (pin 23). At "off-hook" the first priority of the circuit is to make some current available at the Microprocessor Sup-
ply (pin 23) to charge quickly the external capacitor C3.

This charging current is: $\mathrm{Icpm}=0.7 \times$ (lline -Idem ), where $\operatorname{Idem}=2.6 \mathrm{~mA}$ is the current charging C 1 .
Vmp $=3.95 \mathrm{~V}$ in normal operation and current increases linearly from 0.5 mA min, at lline $=6 \mathrm{~mA}$, to 2.5 mA min, at lline $=27 \mathrm{~mA}$, remaining stable for higher values of lline.

Figure 9 : Microprocessor Supply Current vs. Line Current.

4.2. MICROPROCESSOR RESET (pin 16). The Microprocessor Reset becomes active when Vmp overcomes $85 \%$ of its nominal level.
It becomes low when Vmp undergoes $84 \%$.
Figure 10.

## 5. PUBLIC / PRIVATE

5.1. A.G.C. OFF (pin 10). An external resistor, R18, applied between pin 10 and ground disconnects the AGC control.

Sending, receiving gain and sidetone compensation
are now independent of the line length and the value of the current Ip, flowing through R18, defines the length of the line for which sidetone is optimized ( $\mathrm{lp}=2.7 \mathrm{~V} / \mathrm{R} 18$ ).

Figure 11.

5.2. SECRET FUNCTION FOR PRIVATE (pins 11 \& 14). The two separate Mute pins allow "Secret Function" (only microphone muted).
As the two controls have different threshold levels, they can be operated :
a) separately through two different control logic,
b) connected in short circuit with a three levels logic ( $\mathrm{Vm}=0 \mathrm{~V}$ speech mode ; $\mathrm{Vm}=1.8 \mathrm{~V}$ microph mute;
$\mathrm{Vm}=3 \mathrm{~V}$ all mute).

## 6. POWER MANAGEMEN AND HANDS-FREE INTERFACE

6.1. Power Management (pin 12). Most of the DC current available from the line will be delivered by the speech circuit at the output Isource (pin 12) through an internal current generator.
Typical valués of this current, lea, are :

- lea $=(0.3 x$ lline $)$ for lline $<22 m A$
- lea $=(0.9 x$ line 13 mA$)$ for line $>22 m A$
(ex: lline $=16 \mathrm{~mA}$ then lea $=4.8 \mathrm{~mA}$
lline $=30 \mathrm{~mA}$ then lea $=14.0 \mathrm{~mA}$
lline $=60 \mathrm{~mA}$ then lea $=41.0 \mathrm{~mA}$

The voltage level at pin 12 must be defined by an external regulator (i.e. : zener) and, if necessary, filtered with a capacitor ( 47 to 220 microF).
In case Vline (at pin 20) approaches $V$ at pin 12, then the internal current source switches off and its DC current is shunt to ground through an internal complementary generator, thus avoiding and negative effect on the AC and DC impedances of the telephone set application.

Figure 12.

6.2. EXTRA RECEIVE OUTPUT (pin 4). The Extra Receive Signal is active also in Receive Mute condition, so allowing the transit of the receive signal from the speech circuit to an external hands-free system even when the earpiece is muted.

The gain at this pin is 30 dB lower than standard Re ceive Output (pin 24).

- $2 / 4$ WIRES INTERFACE WITH

Figure 1 : Test Circuit.

## CIRCUIT DESCRIPTION

## 1. DC-Characteristics

1.1. VC (pin 17). The stabilized voltage Vc is connected to Vline (pin 16) through an internal shunt regulator which presents to the line a high AC impe-
dance at frequencies higher than 200 Hz . At this purpose the value of C1 (at pin 17) must be not lower than 47 microFarad.

Figure 2.

At "Off-hook", with only DC voltage applied to the line terminals, C1 fixes the timing of the line current profile at :

-     - 150mA max for a time shorter than 400 msec (T-charge)
-     - 60mA max in steady state (conversation)

T-charge of 240 msec (typ) is obtained with $\mathrm{C} 1=220 \mu \mathrm{~F}$
T-charge $=\frac{\mathrm{VcxC1}}{\text { Idem }}$ typically .

Figure 3.

1.2. HOOK DETECTION (in ring mode) (pin 12). The DC-characteristic requested to allow off-hook detection by the exchange during ring call may be accomplished:
a) through an analog control (R-C) or
b) by a microprocessor.
a) Application with standard dialer (analog control)

The components R1, R2 and C2 define the timing of the DC characteristic and also limit at 75 mA -peak the line current during decadic dialing.
Optimum values are : $-\mathrm{R} 1 \times \mathrm{C} 2=1.8 \mathrm{sec} ; \mathrm{R} 2 \times \mathrm{C} 2$ $=0.8 \mathrm{sec}$.
To reduce the minimum time between a "on-hook/ off-hook" sequence, R2 may be replaced by a switch to ground.

Figure 4.

b) Application with a microprocessor

Pin 12 may be controlled directly by the micro-controller, through a resistor R1b which replaces R1, R2 and C2.
Figure 5.

1.3. VLINE (pin 16). The line voltage (pin 16) is determined by the value of the external resistor R6 and by the internal current, lint, flowing between Vc (pin
17) and Ground (see also parag. 1.1.) :

$$
\text { VLINE }=\mathrm{Vc}+\mathrm{R} 6 * \text { lint. }
$$

Vc is fixed by design at about 2.6 volts.
lint is reversely related to R 9 (lint $=7.5 \mathrm{~V} / \mathrm{R} 9$ at lLINE $=27 \mathrm{~mA}$ ).
VLINE must be externally adjusted (with R6) to guarantee both DC and AC characteristic in accordance to the french standards. At this purpose it is suggested that Vline equals 5.6 volts at lline $=16 \mathrm{~mA}$. This typical value is obtained with $\mathrm{R} 6=13 \mathrm{Kohm}$.

Figure 6.

1.4. HIGH VOLTAGE CONTṘOL STAGE (pin 13). The behaviour of "HV control" is determined by several conditions, both internal (lline sensor) and external (pins 12 and 17) with the purpose to accomplish the different DC characteristics and transitory conditions imposed by the French specification :
a) steady DC-characteristic and lightnings (pins 12 and 170 N )
b) DC-characteristic at off-hook (pin 12 and 17 grounded)
c) DC-characteristic during decadic dialing (pin 17 grounded)
d) DC-characteristic after off-hook in ringing (pin 12 grounded)
To do that, HV control pin regulates the current injected into the external high voltage transistor stage, requested by the French specification.

Figure 7.

b) pin 12 and 17 grounded

c) pin 12 ON ; pin 17 grounded

d) pin 12 grounded; pin 17 ON .

## 2. Transmission Chain

Figure 8.

2.1. A.G.C. IN TRANSMISSION. The transmission gain between Microphone Input (pin 7) and Vline (pin 16) is internally decreased of 6 dB when the line current varies from 27 mA to 42 mA with a constant AC load of 6000 hms .
2.2. SENDING IMPEDANCE. The impedance of the Output Stage Amplifier, Zout, is determined by the impedance $\mathrm{Z4}$ at pin 3.

$$
\text { Zout = } 10.65 \times \text { Z4. }
$$

The total $A C$ impedance shown to the line is the parallel
Zpar = Zout/Zint//Zext
where:

- Zint $=10 \mathrm{kohm} / / 8.5 \mathrm{nF}$ (internal)
- Zext = R6 // C4 (at pin 16)
2.3. SENDING MUTE. In normal speech operation (Vmute at pin 100.8 V ), the signal at Microphone Input (pin 7) is amplified to Vline (pin 16) with the gains Gec (short line), Gel (long line) or intermediate, depending on lline.
In sending mute condition (Vmute 1.6 V ) these gains are reduced of at least 60 dB . In the same condition DTMF input (pin 6) is activated, with gain Gmf to the line independent from lline.
2.4. ANTISIDETONE BUFFER. The signal coming from the sending preamplifier is internally presented at pin 4 and than buffered to pins 1 and 2 for sidetone cancellatión (see paragraph 3.2.).

## 3. Receive Chain

Figure 9.

3.1. A.G.C. INRECEIVE. As described for the transmission chain, also the receiving gains $G$ r, from pins 1 and 2 to pin 20, have a reduction of 6 dB when lline moves from 27 mA to 42 mA .
3.2. SIDETONE COMPENSATION. The circuit is provided with a double anti-sidetone network to optimize sidetone both at long and short lines.
Before entering pins 1 and 2 , the received signal is attenuated by two attenuating networks:
Zall / Zrl to pin 1 for long lines sidetone compensation,
Zalc / Zrc to pin 2 for short lines sidetone compensation.
Zrl and Zrc define the total receive gains :
a) $\frac{V 20}{V 16}=\operatorname{Grl} \times \frac{\mathrm{Zrl}}{\mathrm{Zrl}+\mathrm{Zall}}$ for long lines
b) $\frac{V 20}{V 16}=\operatorname{Grc} x \frac{\text { Zrc }}{\text { Zrc }+ \text { Zalc }}$ for short lines

Zall and Zalc define the sidetone compensation of the circuit.
The equivalent balancing impedance is given by the formula :

$$
\text { Zal }=\text { K * Zalc }+(1-K) * \text { Zall }
$$

where :

- $K=0$ at lline $=27 \mathrm{~mA}$ or lower (long line)
- K varies from 0 to 1 with lline between 27 mA and 42mA,
- $K=1$ at lline $=42 m A$ or higher (short line).

Calculations to define Zall and Zalc are :
a) Zall $=70 \times$ R5 $\times \frac{\text { Zline(long) // Zext // Zint // Zout }}{\text { Zout }}$
b) Zalc $=70 \times$ R5 $x$

where:

- Zext = R6 // C4 // (Zelectret) (at pin 16)
- Zint $=10 \mathrm{Kohms} / / 8.5 \mathrm{nF}$ (internal impedance)
- Zout = 10.65 * Z4 (at pin 3 ; see paragr. 2.2.)
- Zline (short) and (long) are the impedances of the line at 0 Km and 3.5 Km .
- R5 = 5.1 Kohm $\pm 1 \%$
3.3. AC IMPEDANCE. The total AC impedance of the circuit to the line is :
Zpar = Zout//Zint/Zext//Zalc//Zall (see par. 2.2. and 3.2.)
= Zout/Zint/Zext (Zalc, Zall >> Zpar)
3.4. RECEIVE MUTE (AND CONFIDENCE LEVEL). When the receive channel is muted (Vmute at pin 102.7 V ) the receive gain is reduced of 60 dB minimum.

In this condition an internal connection is activated from line DTMF output (pin 16) to Receive Output (pin 20) with a gain $\mathrm{Gmf}=38.5 \mathrm{~dB}$ to provide acoustic feedback of the DTMF transmission.

## 4. Microprocessor Interface

4.1. MICROPROCESSOR SUPPLY (PIN 19). At "off-hook" the first priority of the circuit is to make some current available at the Microprocessor Supply (pin 19) to charge quickly the external capacitor C3.

Figure 10.

This charging current is : Icpm = $0.7^{*}$ (lline - Idem), where Idem $=2.6 \mathrm{~mA}$ is the current charging C 1 .
Vmp $=3.25 \mathrm{~V}$ in normal operation and current increases linearly from 0.5 mA min, at lline $=6 \mathrm{~mA}$, to 2.5 mA min , at lline $=27 \mathrm{~mA}$, remaining stable for higher values of lline.

## 5. Public/Private

5.1. A.G.C. OFF (PIN 9). An external resistor, R18, applied between pin 9 and ground disconnects the AGC control.
Sending, receiving gain and sidetone compensation are now independent of the line lenght and the value of the current lp, flowing through R18, defines the lenght of the line for which sidetone is optimized ( $\mathrm{lp}=2.7 \mathrm{~V} / \mathrm{R} 18$ ).

Figure 11.

5.2. SECRET FUNCTION (PIN 10). The Mute pin allows "Secret Function" (only microphone muted), when the circuit is used for private market.
As the control of sending and receiving must have different threshold levels, it can be operated with a three levels logic:
a) $\mathrm{Vm}=0 \mathrm{~V}$ speech mode ;
b) $\mathrm{Vm}=1.8 \mathrm{~V}$ microphone muted ;
c) $\mathrm{Vm}=3.0 \mathrm{~V}$ all speech muted.
'
$\stackrel{\square}{\div}$

## SPEECH CIRCUIT WITH POWER MANAGEMENT

- 2/4 WIRES INTERFACE WITH
- double antisidetone network
- Rx gain and AC impedance externally programmable
- AGC attack/disconnect points programmable
- DTMF INTERFACE
- 3.3 VOLTS SUPPLY FOR MICROPROCESSOR OR DIALER
- CURRENT SUPPLY FOR LOUDSPEAKER

## DESCRIPTION

The TEA7062 is designed to meet the different european specifications for telephone set in medium and high range equipments.

## CIRCUIT DESCRIPTION

## 1. DC Characteristics

1.1 Vc (pin 15). The stabilized voltage Vc is connected to Vline (pin 14) througth an internal shunt regulator $\mathrm{T} 1, \mathrm{~T} 2$, which presents to the line a high AC impedance at frequencies higher than 200 Hz . At
this purpose the value of C1 (at pin 15) must be not lower than 47 microFarad (suggested value is $100 \mu \mathrm{~F}$ ).
The shunt regulator, T1 and T2, also controls the extra current source, or power management, at pin 10 (see also paragraph 6).

Figure 1.

1.2 VLINE (pin 14). The line voltage (pin 14) is determined by the value of the external resistor R6 and by the internal current, lint, flowing between Vc (pin 15) and Ground (see also paragr. 1.1) :
$\mathrm{V}_{\text {LINE }}=\mathrm{Vc}_{\mathrm{c}}+\mathrm{R} 6 \mathrm{x}$ lint.
Vc is fixed by design at about 2.5 V .
lint is reversely related to R9 (lint $=16 \mathrm{~V} / \mathrm{R} 9+60 \mu \mathrm{~A}$ at lline $>25 \mathrm{~mA}$ ).

VLINE must be externally adjusted (with R6) to guarantee both $D C$ and $A C$ characteristic in accordance to the specific standard of the different administrations.
Another adjustment of the DC characteristic is possible with R9. Increasing the value of R9 causes a decrease of lint and consequently a reduction of the product lint $\mathrm{XR9}$.

Figure 2.

## 2. Transmission Chain

Figure 3.

2.1 A.G.C. IN TRANSMISSION. The transmission gain between Microphone Input (pin 7) and Vline (pin 14) is internally decreased of 6 dB when the line current varies from ILL to ILS with a constant AC load of $600 \Omega$.
The values of ILL (long line current) and ILS (short line current) are programmable through I-start (pin 9) and l-slope (pin 13) (see also paragr. 4).
2.2 SENDING IMPEDANCE. The impedance of the Output Stage Amplifier, Zout, is determined by the impedance Z4 (at pin 3).

$$
\text { Zout = } 10.65 \times \mathrm{Z} 4 .
$$

The total $A C$ impedance shown to the line is the parallel
Zpar = Zout/Zint//Zext
where:

- Zint $=10 \mathrm{k} \Omega / / 8.5 \mathrm{nF}$ (internal)
- Zext = R6//C4 (at pin 14)
2.3 SENDING MUTE. In normal speech operation (Vmute at pin $12<0.8 \mathrm{~V}$ ), the signal at Microphone Input (pin 7) is amplified to Vline (pin 14) with the gain Gs (long line) or up to 6dB lower (shorter lines) depending on AGC control (see paragr. 4).
In sending mute condition (V12>1.6V) these gains are reduced of at least 60 dB . In the same condition, DTMF input (pin 6) is activated, with gain Gmf to the line independent from line.
2.4 ANTISIDETONE BUFFER. The signal coming from the sending preamplifier is intemally presented at pin 4 and than buffered to pins 1 and 2 for sidetone cancellation (see paragraph 3.2).

## 3.Receive Chain

Figure 4.

3.1 A.G.C. IN RECEIVE. As described for the transmission chain, also the receiving gains Gr , from pins 1 and 2 to pin 24, have a reduction of 6 dB when lline moves from ILL to ILS (see also paragr. 4).
3.2 SIDETONE COMPENSATION. The circuit is provided with a double anti-sidetone network to optimize both at long and short lines.
In case double antisidetone network is not requested by the application needs, pins 1 and 2 can be connected to each other and 5 external passive components can be saved (ZALL and ZRL).
Before entering pins 1 and 2 , the received signal is areduced by the two attenuating networks :
-ZALL/ZRL to pin 1 for long lines sidetone compensation,
-ZALS/ZALS to pin 2 for short lines sidetone compensation.
ZRL and ZRC define the total receive gains :
a) $\frac{\mathrm{V} 18}{\mathrm{~V} 14}=\operatorname{Gr} \mathrm{x} \frac{\mathrm{ZRL}}{\mathrm{ZRL+ZALL}}$ for long lines
b) $\frac{\mathrm{V} 18}{\mathrm{~V} 14}=(\mathrm{Gr}-6 \mathrm{~dB}) \times \frac{\mathrm{ZRS}}{\mathrm{ZRS}+\mathrm{ZALS}}$ for short lines

ZALL and ZALS define the sidetone compenstaion of the circuit.
The equivalent balancing impedance is given by the formula:
$Z A L=K \times Z A L S+(1-K) \times Z A L L$ where:
$-\mathrm{K}=0$ at lline = ILL or lower (long line)
$-K$ varies from 0 to 1 with lline between ILL and ILS
$-\mathrm{K}=1$ at lline = ILS or higher (short line).
Calculations to define ZALL and ZALS are :
a)

ZALL $=70 \times R 5 x$
$\frac{\text { Zline (long)//Zext/Zint/Zout }}{\text { Zout }}$
b)

ZALS $=70 \times$ R5 $x$
$\underline{\text { Zline (short)//Zext//Zint//Zout }}$
where:

- Zext = R6//C4//(Zelectret) (at pin 11)
- Zint $=10 \mathrm{Kohms} / / 8.5 \mathrm{nF}$ (internal impedance)
- Zout = 10.65 * Z4 (at pin 3 ; see paragr. 2.2)
- Zline (short) and (long) are the impedances of the line at minimum and maximum line length
- R5 = $5.1 \mathrm{Kohm} \pm 1 \%$
3.3 AC IMPEDANCE. The total AC impedance of the circuit to the line is :
ZAC = Zout/Zint//Zext/ZALS//ZALL (see par. 2.2 and 3.2)
ZAC = Zout/Zint/ZZext (ZALS, ZALL>>ZAC)
3.4 RECEIVE MUTE (and confidence level). When the receive channel is muted (Vpin $12>2.7 \mathrm{~V}$ ) the receive gain is reduced of 60 dB minimum.

In this condition an internal connection is activated from line DTMF output (pin 16) to Receive Output
(pin 18) with a gain $\mathrm{Gmf}=32 \mathrm{dBto}$ provide acoustic feedback of the DTMF transmission.

## 4. A.G.C. and Sidetone Programming

## Figure 5.

(dB)
4.1 PROGRAMMABLE CONTROLS. AGC and sidetone attack and disonnect points (or currents) are programmable externally through two independents pins, I-start (pin 19) and l-slope (pin 13).
4.2 I-START (pin 9). An external resistor RLL connected between l-start (pin 9) and Microprocessor Supply (pin 17) controls the attack point of AGC and ZAL (antisedetone Z ).
ILL is the line current at which the control starts. Formulas for ILL and RLL with R9 $=100 \mathrm{~K}$ are :
ILL $\frac{2880}{\text { RLL }}+11 \mathrm{~mA}$
RLL $\frac{2880}{(\mathrm{ILL}-11 \mathrm{~mA})}$

### 4.3 I-SLOPE (pin 13)

An external resistor RLS connected between I-slope (pin 13) and Microprocessor Supply (pin 17) controls the disconnect point of AGC and ZAL (antisidetone Z). ILS is the line current at which the control stops. Formulas for ILS and RLS with R9 $=100 \mathrm{~K}$ are :

ILS $=\frac{4680}{\text { RLS }}+\mathrm{ILL} ;$

RLS $=\frac{4680}{(\text { ILS - ILL) }}$
4.4 A.G.C. OFF (pin 9 and 13). Programming ILL and ILS respectively higher than 70 mA and 450 mA is forcing the IC in AGC OFF Condition.
Suggested external components are : RLL = 51 kohm and RLS = 10Kohm.
Sending, receiving gain and sidetone compensation are so independent of the line lenght. Pins 1 and 2 can be connected to each other saving 5 passive external components at pin 2.
4.5 SECRET FUNCTION FOR PRIVATE (pin 12). The two separate thresholds for sending and Receiving Mute (pin 12) allow "Secret Function" (only microphone muted).
Pin 12 can be set :
a) between 0 V and 0.8 V for speech mode,
b) between 1.6 V and 2.1 V for "secret" mode (micro phone muted),
c) between 2.7 V and 3.3 V for "all muted" mode

## 5. Microprocessor Interface

5.1 MICROPROCESSORSUPPLY (pin 17). At "offhook" the first priority of the circuit is to make some current available at the Microprocessor Supply (pin 17) to charge quicly the external capacitor C 2 .

This charging current is lcpm $=0.6 \times$ lıine.
T-charge of about 1 msec is necessary, with
$\mathrm{C} 2=4.7 / \mu \mathrm{F}$, to charge pin 17 at the specified value of 3.3 V typical :

T-charge $=\frac{3.3 \mathrm{~V} \times \mathrm{C} 2}{0.6 \times \text { LINE }}$ typically.
Vmp $=3.3 \mathrm{~V}$ in normal operation and current increases linearly from 0.5 mA min , at $\operatorname{lLINE}=6 \mathrm{~mA}$, to 2.5 mA , at $\operatorname{lLINE}=25 \mathrm{~mA}$, remaining stable for higher values of line.

Figure 6.

## 6. Power Management

6.1 POWER MANAGEMENT (pin 10). Most of the DC current available from the line be delivered by the speech circuit at the output Isource (pin 10) through an internal current generator.
Typical values of this current, lea with $R 9=100 \mathrm{~K}$, are:

$$
\begin{aligned}
& \text { lea }=(0.3 \times \text { xLINE }) \\
& \text { lea }=(0.9 \times \text { ILINE }-10 \mathrm{~mA}) \quad \text { for } \text { LINE }<16.5 \mathrm{~mA} \\
& (\mathrm{ex}: \text { ILINE }=16 \mathrm{~mA} \text { then lea }=5 \mathrm{~mA}
\end{aligned}
$$

lIINE $=30 \mathrm{~mA}$ then lea $=17 \mathrm{~mA}$
ILINE $=60 \mathrm{~mA}$ then lea $=11 \mathrm{~mA}$ ).
The voltage level at pin 10 must be defined by an external regulator (i.e. : zener) and, if necessary, filtered with a capacitor ( 47 to 220 microF):
In case VLINE (at pin 14) approaches voltage at pin 10, then the internal current source switches off and its DC current is shunt to ground through an internal complmentary generator, thus avoiding any negative effect on the AC and DC impedances of the telephone set application.

- EXTENSION TONE RINGER MODULES
- ALARMS OR OTHER ALERTING DEVICES

## DESCRIPTION

The ML8204/ML8205 tone ringers are monolithic devices, each incorporating two oscillators, an output amplifier and a power supply control circuit. The oscillator frequencies can be adjusted over a wide range by selection of external components. One oscillator, normally operated at a low frequency (fL), causes the second oscillator to alternate between its nominal frequency ( $\mathrm{f}_{\mathrm{H} 1}$ ), and a related higher frequency ( $\mathrm{f}_{\mathrm{H}}$ ). The resulting output is a distinctive "warbling" tone. The output amplifier will drive either a transformer coupled loudspeaker or a piezo-ceramic transducer. The device can be powered from a telephone line or a fixed d.c. supply. The power supply control circuit has built-in hysteresis to prevent false triggering and rotary dial "chirps". The ML8204 can be triggered externally under logic control. The ML8205 has provision for adjustment of the power supply initiation current.

## FUNCTIONAL DESCRIPTION

The M8204/ML8205 Tone Ringers are primarily intended for use as replacements for the mechanical bell in telephone sets. Each incorporates two oscillators, an output amplifier and a power supply control circuit. The devices can be powered directly from the telephone line using the a.c. ringing voltage, or they may be powered from a separate d.c. supply. The output amplifier is capable of driving a wide range of load impedances when powered from a low impedance supply. The power supply control circuit provides the hysteresis required to ensure positive triggering of the device and to prevent transient triggering due to dial pulsing.
As the power supply voltage to the ML8204/ML8205 is increased up to the supply initiation voltage ( $\mathrm{V}_{\text {sI }}$ ), the supply current also increases up to ( $\mathrm{lsi}_{\mathrm{s}}$ ). When $V_{\text {SI }}$ is exceeded, oscillation begins and the static power supply current decreases (see fig. 2a). The low frequency oscillator (LFO) oscillates at a rate ( fL ) controlled by an external resistor and capacitor. The frequency can be determined using the relation $f_{L}=$ $1 /(1.234 R C)$ where $R$ is the value of the resistor connected between pins 3 and 4 , and $C$ is the value of the capacitor connected between pin 3 and ground.
The output of the LFO is internally connected to the switching threshold circuitry of the high frequency (HFO). When the output of the LFO is high, HFO oscillates at its nominal rate ( $\mathrm{f}_{\mathrm{H}}$ ), described by the relation $f_{H 1}=1 /(1.515 R C)$ where $R$ is the value of the resistor connected between pins 6 and 7 , and $C$ is the value of the capacitor connected between pin 6 and ground. When the output of the LFO is low, the HFO oscillates at a higher rate ( $\mathrm{f}_{\mathrm{H}}$ ) described by the relation $\mathrm{fH}_{2}=1.25 \mathrm{fH}_{1}$. Thus the LFO sets the warbling rate : the rate at which the HFO switches between the two tone frequencies $\mathrm{f}_{\mathrm{H} 1}$ and $\mathrm{f}_{\mathrm{H} 2}$. Oscillation continues until the supply voltage decreases below the sustaining voltage ( $\mathrm{V}_{\text {sus }}$ ). At this point, the power supply current undergoes a step increase (from Isus), and then ramps down in accoardance with the supply voltage.
In normal applications, Trigger in (pin 2) of the ML8204 is left open circuit. This pin allows external
triggering of oscillation of the ML8204 at supply voltages in the range $\mathrm{V}_{\text {sus }} \leq \mathrm{V}_{\mathrm{s}} \leq \mathrm{V}_{\text {si. }}$. To do so, a voltage at least equal to the minimum trigger voltage ( $V_{\text {TR }}$ ) must be applied to pin 2.
Triggering the device is accomplished by sourcing a minimum current (lTR) into pin 2 . This current must be limited to prevent damage to the triggering circuit. Tone ringer oscillation may also be inhibited at supply voltages in the range $\mathrm{V}_{\mathrm{si}}<\mathrm{V}_{\mathrm{s}} \leq \mathrm{V}_{\mathrm{s}(\text { max })}$ by applying a maximum disable voltage (VDIS) to pin 2. Disabling is accomplished by sinking a minimum current (IDIS) out of pin 2. (See Applications Section for details on the operation and use of the Trigger in pin).
The ML8205 requires the connection of a resistor, RsL, fo program the slope of its supply current versus supply voltage characteristic prior to triggering ( $\mathrm{V}_{\mathrm{s}} \leq \mathrm{V}_{\mathrm{si}}$ ). This in turn determines the maximum supply initiation current (lsi drawn at the initiation voltage ( $\mathrm{V}_{\text {sil }}$ ). Programming is accomplished by connecting a slope determining resistor, RsL, between pin 2 and ground. The value of $I_{\text {si }}$ varies inversely with the value of RsL. This feature can be used to control effective impedance presented to the telephone line by the ringer circuit. (See Applications section for detailed description on the operation and use of the RsL pin).
The output amplifier of the ML8204/ML8205 is capable of driving a wide range of load impedances when driven from a low source impedance power supply. When the device is powered from a telephone line, load impedance should be kept fairly high (800 or greater) to prevent power supply regulation problems. A transformer is thus required for driving loudspeakers as is an output coupling capacitor. Piezo-ceramic transducers may be driven directly. However, the tone frequencies $\mathrm{f}_{\mathrm{H} 1}$ and $\mathrm{f}_{\mathrm{H}}$ must normally be set higher (around 2 KHz ) to ensure that the transducer delivers sufficient acoustic power. (Suitable piezo-ceramic transducers typically have maximum efficiency around 2 KHz ). It is also necessary to connect a zener diode in parallel with the transducer to limit voltage surges generated by the transducer during mechanical shocks.

## APPLICATIONS

TYPICAL TELEPHONE OR EXTENSION TONE RINGER CIRCUIT
The circuit shown in fig. 3 illustrates the use of the ML8204/8205 devices in a typical telephone or extension tone ringer application. The a.c. ringing voltage appears across the TIP and RING inputs of the circuit and is attenuated by capacitor $\mathrm{C}_{1}$ and resistor $R_{1}$. $C_{1}$ also provides isolation from d.c. voltages on the line. After full wave rectification by the diode bridge $\mathrm{BR}_{1}$, the waveform is filtered by capacitor $\mathrm{C}_{4}$ to provide a d.c. supply for the tone ringer chip. As this voltage exceeds the initiation voltage, $\mathrm{V}_{\mathrm{si}}$, oscillation starts. With the components shown, the output frequency chops between $512 \mathrm{~Hz}\left(\mathrm{f}_{1}\right)$ and $640 \mathrm{~Hz}\left(\mathrm{f}_{\mathrm{H} 2}\right)$ at a $10 \mathrm{~Hz}(\mathrm{f} \mathrm{L})$ rate. The loudspeaker load is coupled through a $1300 \Omega$ to $8 \Omega$ transformer. While the output impedance of the ML8204 is quite low, the load impedance must be kept fairly high. This is to prevent d.c. power supply regulation problems due to high source impedance of the telephone line and coupling components $\mathrm{C}_{1}$ and $\mathrm{R}_{1}$. The output coupling capacitor $\mathrm{C}_{5}$ is required with
transformer coupled loads. The value shown ( $0.22 \mu \mathrm{~F}$ ) presents a high enough impedance at the nominal ringing frequency to allow connection of fairly low impedance loads without upsetting the supply regulation. If the load impedance is large enough, then the value of this capacitor can be increased to couple more power to the load without upsetting the power supply to the ML8204. Potentiometer $P_{1}$, is used to adjust the audio amplitude and resistor $R_{4}$ is a current limiting resistor. Resistor $R_{5}$ is a quenching resistor used to limit back emf generated by the inductive load when ringing stops. When driving a piezo-ceramic transducer type load, the coupling capacitor $\mathrm{C}_{5}$ is not required. However, a current limiting resistor is required as is a 29 V zener diode in parallel with the transducer. This diode limits the voltage transients than can generated by mechanical shocking of a piezo-ceramic transducer. The electrical characteristics shown in Table 2 indicate typical performance of this circuit. The incoming ringing voltage and frequency are determined by the telephone system.

## USE OF TRIGGER IN (pin 2 ML8204)

Pin 2 of the ML8204 may be used to a) externally trigger oscillation for voltages in the range $\mathrm{V}_{\text {sus }} \leq \mathrm{V}_{s}$ $\leq V_{\mathrm{si}}$, or b) disable ringer operation. The equivalent circuit at pin 2 is shown in Fig. 5. The ringer circuit can only oscillate when $Q_{1}$ is conducting. Normally when supply voltage $\mathrm{V}_{\mathrm{s}}$ exceeds the supply initiation voltage $\left(\mathrm{V}_{\mathrm{si}}\right)$, base current flows into $\mathrm{Q}_{1}$, via $\mathrm{D}_{2}$ and $D_{1}$ causing $Q_{1}$ to conduct. This continues until $\mathrm{V}_{\mathrm{s}}$ is taken below the minimum sustaining voltage ( $V_{\text {sus }}$ ).
The ML8204 can be made to oscillate when powered from supply voltages in the range $\mathrm{V}_{\text {sus }} \leq \mathrm{V}_{\mathrm{s}} \leq \mathrm{V}_{\text {si }}$.

Oscillation is ensured by forcing a current $I_{T R}(10 \mu \mathrm{~A}$ $\leq I_{T R} \leq 1 \mathrm{~mA}$ ) into pin 2 to provide base current to $\mathrm{Q}_{1}$. This requires the voltage applied to pin 2 to exceed $V_{T R}$ where $V_{T R}$ is the sum of the zener voltage of $D_{3}$, the forward voltage drop of $D_{2}$ and the $V_{B E}$ of $\mathrm{Q}_{1}$ (typically 11 V ). The required current drive can be provided by connecting a resistor $R_{E}$ between pin 1 and $\mathrm{V}_{\mathrm{S}}$ (Fig. 5a) ; where: $20 \mathrm{~K} \Omega \leq \mathrm{R}_{\mathrm{E}} \leq\left(\mathrm{V}_{\mathrm{s}}\right.$ $11) / 10 \mathrm{M} \Omega$. To operate the ML8204 from a d.c. 12 V supply, $\mathrm{Re}_{\mathrm{E}}$ should be typically 50 K . This mode of operation can also be used to reduce the effective value of the $\mathrm{V}_{\mathrm{si}}$, by inserting a zener diode in series with $R_{E}$ (fig. 5b). This modifies the initiating voltage to $V_{\text {si }}(E f f)=V_{T R}+V_{E}+10 R_{E}\left(R_{E}\right.$ is in $\left.M \Omega\right)$.

Figure 4 : Pin 2 Input Equivalent Circuit.

Figure 5a : Enabling Oscillation of the ML8204 for Supply Voltages less than $\mathrm{V}_{\text {si }}$.

Figure 5b : Reducing the Effective Value of $\mathrm{V}_{\mathrm{si}}$ for the ML8204

Oscillation of the ML8204 may be inhibited for voltages in the range $\mathrm{V}_{\mathrm{si}}<\mathrm{Vs} \leq \mathrm{V}_{\mathrm{s}(\text { max })}$ by sinking the current from $D_{1}$, starving $Q_{1}$ of base current. This is achieved by either a) grounding pin 2 (fig. 6a), or b) applying a voltage VINH via a resistor $\mathrm{R}_{1}$ to pin 2 (fig. 6b) to ensure that :
$V_{\text {DIS }} 0.8 \mathrm{~V}$, and loIS $=\frac{\mathrm{V}_{\text {DIS }}-\mathrm{V}_{\text {INH }}}{R_{1}} \geq 40 \mu \mathrm{~A}$.
Figure 6 : Inhibiting Oscillation of the ML8204.

When driven from a fixed d.c. supply, oscillation of the ML8204 may be gated on or off by CMOS or TTL logic as shown in Fig. 7a and Fig. 7b respectively.

Figure 7a : Gating the ML8204 from CMOS.

Figure 7b : Gating the ML8204 from TTL.

## PROGRAMMING THE ML8205 INITIATION CURRENT

Pin 2 of the ML8205 requires connection of an external resistor RsL (fig. 8), which is used to program the slope of the supply current vs, supply voltage characteristic, and hence the supply current up to the initiation voltage $\left(V_{\text {sil }}\right)$. This initiation voltage remains constant independent of RsL. The supply initiation current ( $\mathrm{lsi}_{\mathrm{s}}$ ) varies inversely with RsL, decreasing for increasing values of resistance. Thus, increasing the value of RsL will decrease the amount of a.c. ringing current required to trigger the device, As such, longer subscriber loops are possible since less voltage is dropped per unit length of loop wire due to the lower current level. RSL can also be used to compensate for smaller a.c. line coupling capaci-
tors (providing higher impedance) which can be used alter the ringer equivalence number of a tone ringer circuit.
The graph in fig. 9a illustrates the variation of supply current with supply voltage of the ML8205. Three curves are drawn to show the change in the slope of the I-V characteristic with RsL. Curve B ( $\mathrm{R}_{\mathrm{SL}}=$ $6.8 \mathrm{~K} \Omega$ ) shows the $\mathrm{I}-\mathrm{V}$ characteristic for the ML8204 tone ringer. Curve A is a plot with $\mathrm{RSL}=5.0 \mathrm{~K} \Omega$ and shows an increase in the current drawn up to the initiation voltage $\mathrm{V}_{\text {si }}$. The I-V characteristic after initiation remains unchanged. Curve C illustrates the effect of increasing RsL to $13.0 \mathrm{~K} \Omega$. Initiation current decreases but again current after trigging is unchanged. The variation of $\mathrm{I}_{\mathrm{si}}$, with RSL is illustrated in fig. 9b.

Figure 8 : Adjusting Isi by Varying RsL.

Figure 9a: I-V Slope Change Due to RsL.

Figure 9b : Supply Initiation Current. (Isi) vs. Rst.

MITEL F.C.C. APPROVED TONE RINGER MODULE USING ML8205

The Mitel tone ringer module (CM3215) using the Mitel ML8205 tone ringer chip in the circuit below (fig. 10) has been approved by the F.C.C. (F.C.C. reg. number BN285B673550TN). The circuit has been given a ringer equivalence of 0.7 B . This accomplished by increasing the value of RsL to $13 \mathrm{~K} \Omega$ which reduces the supply initiation current ( $\mathrm{Isic}_{\mathrm{i}}$. This reduction in $\mathrm{I}_{\mathrm{s}}$ allows the use of higher line coupling components ( $\mathrm{R}_{1}=8.2 \mathrm{~K} \Omega$ ) while ensuring sufficient voltage drop between pins 1 and 5 of the ML8205 for triggering. The 5.1 V zener diode $\mathrm{D}_{1}$ presents a high impedance to low level signals on the tele-
phone line while allowing tone ringer powering from high level rigging voltages.

## TRANSIENT OVERVOLTAGE TESTING OF THE ML8204 TONE RINGER

The following tests were performed to investigate the ability of the ML8204 to withstand transients on its power supply rails. All tests were performed using the circuit shown in fig. 11 with transient voltage pulses of the form shown in fig. 12. After each application of a transient pulse, functionality of the device was checked by switching $S_{1}, S_{2}$, and $S_{3}$ to the configuration shown in fig. 11.

Figure 10 : F.C.C. Approved Tone Ringer Circuit.

Figure 11 : ML8204 Test Circuit (power supply transient).

The device was tested in two ways by applying pulses : 1) directly into the ML8204 power supply pins, and 2) to the complete ringer circuit TIP and RING inputs. In the first case with $\mathrm{S}_{1}$ in position " b ", a series of pulses with magnitudes $(\mathrm{V})$ from 30 V upwards applied from the TF152 until the ML8204 falled to operate. This was repeated for 10 devices. The unloaded value of $V$ at which the devices ceased to operate varied from 84 to $88 \mathrm{~V}(\mathrm{~V}$ BK). Subsequently a number of devices were tested by applying 70 V pulses to each device. Instability was noted in some devices after 100 pulse applications. All devices ceased to function after 172 to 203 pulse applications. A further set of devices were tested with 64 V pulses. All devices withstood 300 pulse applications without any sign of degradation. In the second test, with switches $S_{2}$ and $S_{3}$ in position "b" and $S_{1}$ in position "a", 800 and 1500 V pulses were repeatedly applied to the TIP and RING inputs of the
circuit. No degradation of the devices' operation was observed.
SINGLE TONE OPERATION OF" THE ML8204/ML8205
The ML8204/ML8205 can be'made to oscillate at one or the other of its output tone frequencies $\mathfrak{f}_{\mathrm{H} 1}$ or $\mathrm{f}_{\mathrm{H} 2}$. To do so, the tone frequency determining components are connected to pins 6 and 7 as normally done. Pin 3 is used as a control input: When pin 3 is connected to $\mathrm{V}_{\mathrm{s}}$, the output (pin 6) will oscillate at the $\mathrm{f}_{\mathrm{H} 1}$ frequency. Conversely, when pin 3 is at ground, the output will oscillate at the fH2 frequency. The output can thus be switched between $\mathrm{f}_{\mathrm{H} 1}$ and $\mathrm{f}_{\mathrm{H} 2}$ externally by applying a control signal to pin 3. The low frequency oscillator may also be used separately by connecting the frequency determining components between pins 3 and 4 as normally done. The output is taken from pin 4. However, this is a fairly high impedance output.

Figure 12: Typical Transient Tset Waveform.

Figure 13 : Single Tone Operating of ML8204/ML8205.

## TYPICAL APPLICATION CIRCUITS FOR USE WITH A PIEZO-ELECTRIC TRANSDUCER

Feedback from a piezo-electric transducer can cause spurious oscillations on the output of a ML8204/5 tone ringer. These oscillations corrupt the normal two-tone output and change as the ringer switches off.
The oscillations occur because the piezo electric transducer resonates at its characteristic frequency. If the resonant amplitude is sufficient to pull pin 8 one bipolar threshold below pin 5 then the tone ringer may give a short spurious pulse.
This effect can be eliminated by using a bypass capacitor across the transducer as shown in fig. 14. The size of this capacitor is obviously dependent on the piezo-electric transducer used, but a value of $0.1 \mu \mathrm{~F}$ is usually sufficient.
It is possible under specific conditions for a ML8204/5 tone ringer with a piezo-electric load to continue oscillating after the ringing voltage stops.

The ringer can be powered by the smoothing capacitor which is across pins 1 and 5 (see fig. 14). This causes the device to switch off slowly and since the output frequencies shift by about a musical semitone before oscillation stops, the output can have an unpleasant tail-off.

To eliminate this, a simple monitor can be used which switches the output off when ringing stops. fig. 16 shows a circuit which works with an ML8204. When ringing voltage is applied from the line, pin 2 is held between 2 and 10 V and the device functions normally. When ringing stops, pin 2 is pulled to ground and the ML8204 switches off.

There is no enable on the ML8205 corresponding to pin 2 on the ML8204. Fig. 16 shows a circuit which does not require the enable pin. The output is switched through an NPN transistor instead. During ringing the base of the transistor is forward biased and the load is enabled. When ringing stops the transistor switches off and deactivates the load.

## ELECTRONIC TWO-TONE RINGER

- LOW CURRENT CONSUMPTION, IN ORDER TO ALLOW THE PARALLEL OPERATION OF 4 DEVICES
- INTEGRATED RECTIFIER BRIDGE WITH ZENER DIODES TO PROTECT AGAINST OVERVOLTAGES
- LITTLE EXTERNAL CIRCUITRY
- TONE AND SWITCHING FREQUENCIES ADJUSTABLE BY EXTERNAL COMPONENTS
- INTEGRATED VOLTAGE AND CURRENT HYSTERESIS
- BRIDGE OUTPUT CONFIGURATION

## DESCRIPTION

L3240 is a monolithic integrated circuit designed to replace the mechanical bell in telephone sets, in connection with an electro acoustical converter. The device can drive either directly a piezo ceramic converter (buzzer) or a small loudspeaker. In this case a transformer is needed. The two tone frequencies generated are switched by an internal oscillator in a fast sequence and made audible across output amplifiers in the transducer ; both tone frequencies and the switching frequency can be externally adjusted.
The supply voltage is obtained from the $A C$ ring si-

gnal and the circuit is designed so that noise on the line or variations of the ringing signal cannot affect the correct operation of the devices.
The output bridge configuration allows to use a high impedance transducer with acoustical results much better than in a single ended configuration.
The two outputs can also be connected independently to different converters or actuators (acoustical, opto, logic).

## DESCRIPTION

LS1240 and LS1240A are monolithic integrated circuits designed to replace the mechanical bell in telephone sets in connection with an electro-acoustical converter. Both devices can drive directly a piezoceramic converter (buzzer).
The output current capability of LS1240A is higher than LS1240. For driving a dynamic loudspeaker LS1240 needs a transformer, while LS1240A, needs a decoupling capacitor.
No current limitation is provided on the output stage of LS1240A, so a minimum load DC of $50 \Omega$ is adviced.
The two tone frequencies generated are switched by an internal oscillator in a fast sequence and made audible across an output amplifier in the loudspeaker, both tone frequencies and the switching frequency can be externally adjusted.

The supply voltage is obtained from the $A C$ ring signal and the circuit is designed so that noise on the line or variations of the ringing signal cannot affect correct operation of the device.

ORDER CODE : M764A B1

## PIN CONNECTION

 level can be externally programmed to increase gradually during the first three bursts. Output tone stability and the bandpass filter corner frequencies are guaranteed by a crystal controlled oscillator.
The M764A is available in 16 pin dual in-line plastic.

## DESCRIPTION

The M764A is a high performance electronic ringer suitable for application in standard and parallel connection telephones; it can also be used as an alarm indicator. An incorporated bandpass filter prevents spurious ringing caused by transients and dialling pulses. Pin-selectable options permit three, two and single tone sequences.
The output stage allows direct drive of both piezoceramic and dynamic transducers. The output tone The Mis

## FUNCTIONAL DESCRIPTION

## MAIN OSCILLATOR

The main oscillator has been designed to be driven either by an external RC network or by a ceramic resonator (see fig. 1) :
The accuracy of the output tones and of the bandpass filter characteristics are determined by the accuracy of the main oscillator frequency.
The crystal guarantees good performance over the whole temperature range with no external trimmer. The main oscillator as well as the sweep oscillator are maintained in a stand-by condition or forced to run according to table 1.

## SWEEP OSCILLATOR

The sweep oscillator (fig. 2) controls the repetition rate of the output tone sequence. The output repetition period is given by

$$
\mathrm{T}_{\text {rep }}=\frac{384}{\mathrm{~F}_{\text {sweep oscill. }}}
$$

## OUTPUT TONE ACTIVATION (pins FEN, EIN, FRI)

The output stage is enabled by the signal OE (output enable) under control of pins FEN, EIN, FRI as shown in table 1, and fig. 3.
Pin FEN and EIN are standard C-MOS inputs.
Pin FRI has a pull-down resistor of approximately $300 \mathrm{~K} \Omega$.

## OUTPUT ENABLE (OE)

The output enable pin (OE) can be used in special application to drive a LED or any external circuit to indicate that an incoming ringing signal has been detected by the tone ringer as in automatic responders.
OE timing diagrams are shown in table 1.
The OE output stage configuration is shown in fig.4.

Figure 1 : a) Crystal Controlled Oscillator.

Figure 2.

Figure 3 : Timing Diagram.

Figure 4.

Table 1.

## TONE OUTPUTS (TO, TO)

Two complementary outputs are provided to drive in a bridge configuration both piezoceramic and dynamic transducers (see fig. 5).
The configuration of the output buffer is shown in fig. 6.
The output waveform is a square wave with $50 \%$ duty cycle.

The generated tone level can be constant or can be gradually increased up to the max. level during the detection of the first three ring signals.
This function has been implemented controlling the output voltage swing that can be VDD for max. output level, 0.4 VDD for the intermediate output level and 0.1 $\mathrm{V}_{\mathrm{DD}}$ for the lowest output level.

## OUTPUT DRIVE MODE (ODM)

The output level is constant if this pin is a logical 0 : it gradually increases to the max. level if this pin is a logical 1 : the sequence can take place if after the first ring signal during the ring tone pause period the supply does not fail below the power on reset threshold ( 5.5 V ) and always starts from the lowest level.

## TYPICAL APPLICATIONS

Figure a : Tone Ringer for Standard telephone Applications.

If pin EIN is connected to $V_{D D}$ the ringer is activated by frequencies upper than 20 Hz .

- In both cases the volume potentiometer can be avoided connecting the ODM to $V_{D D}$ allowing the gradually increase of the ringer volume in
three steps.
- The number of the output available tones and their frequencies are controlled by ABC pins according to table 2.

Figure b : Tone Ringer for Alarm,Buzzer or Ring Tone Detection in Centralized Equipments.

ANTI TAPPING APPLICATION
In the anti-tapping application an input current threshold is established.

- NOISE SUPPRESSION BY DIGITAL FREQUENCY FILTER AND LEVEL DETECTOR
- USES LOW COST CERAMIC RESONATOR FOR MAIN OSCILLATOR
- REPETITION RATE OFTONE SEQUENCE ADJUSTABLE BY RC TIME CONSTANT

## DESCRIPTION

The SAA1094 replaces the electromechanical telephone bell and calls the subscriber by a melodic tone sequence. It derives its power supply by rectifying the ac ringing signal, requires only a minimum of additional components and is compatible with the conventional telephone network.

## GENERAL DESCRIPTION

The SAA1094 replaces the customary electromechanical telephone bell and calls the subscriber by a melodic tone sequence, using a small magnetic or piezo-ceramic sound transducer. The melody ringer circuit, together with its transducer is powered by the ringing current from the enge. This makes it compatible with the conventional telephone network and, in addition, no battery or mains connections are needed (fig. 2). It is also possible to apply a DC signal instead of the AC ringing signal (fig. 3). As shown in fig. 2 and 3 the amount of additional components is reduced to a minimum.

## FUNCTIONAL DESCRIPTION OF THE TONE RINGER CIRCUIT

## POWER SUPPLY

The tone ringer circuit (fig. 2) derives the power required for its operation from the ringing AC supplied by the exchange via linea $a$ and $b$. Together with the loop resistance, the specified $1 \mu \mathrm{~F}$ isolating capacitor and a $2.2 \mathrm{k} \Omega$ resistor is needed to ensure a minimum impedance.
The supplied alternating current is fed to pins 5 and 7 of the tone ringer and is rectified by means of an
integrated bridge circuit in the SAA1094. The rectified current charges the electrolytic capacitor at pin 4 and 6. The direct voltage V 6-4 generated across this capacitor is the supply for the internal circuit. It mainly depends on the loop resistance and on the ringing frequency. Its maximum value is limited by an internal Zener diode to about 20 V .

## CLOCK SIGNAL GENERATION

The clock oscillator, integrated in the SAA1094 tone ringer Ic requires only an inexpensive ceramic resonator connected to pins 2 and 3 , for example the 455 KHz type Murata CSB 455E. The frequency of this oscillator is used to derive the three input tone frequencies and the clocks for the output frequency comparator.

## MONITORING THE INPUT RINGING FREQUENCY

The frequency fin of the ringing AC supplied to the inputs pins 5 and 7 is monitored in the SAA1094 by a frequency comparator. The result of the frequency comparison is used as one criterion for activiting the tone generator (see section 4 for the other crite-
rion). The circuit generates output tones only if the input ringing signal is inside a specified frequency band. Three different modes can be selected by the option pin 1.
a) Pin 1 unconnected:

In this mode a frequency fin from 23 to 54 Hz will be accepted for producing the output tone sequence.
b) Pin 1 connected to pin $4=0$

In this mode a frequency fin from 12 to 54 Hz will be accepted. Due to this option, the SAA1094 can also be employed in telephone systems having a ringing frequency below 20 Hz .
c) Pin 1 connected to pin $6=1$

In this mode the result of the frequency comparison has no influence. A DC signal can be applied to the SAA1094 at pins 4 and 6 or pin 5 and 7 for producing the output tone sequence.
A digital noise suppression circuit in the SAA1094 ensures that noise signals in the range from OHz to 20 KHz and with a maximum amplitude of 9 V RMS will not affect the correct function of the SAA1094 if the input ringing signal applied to the terminal a and b fig. 2 has an amplitude of 50 V RMS and a frequency in the range specified for producing an output signal.

## VOLTAGE LEVEL DETECTOR

The voltage level V 6-4 is monitored in the SAA1094 and used as another criterion for activiting the tone generator. The tone sequence will be started when V 6-4 increases to a level around 6 V . The tone sequence will be ended when $V 6-4$ decays to a level around 3 V .

## TONE SEQUENCER

The ringing signal produced by the SAA1094 is a sequence which is determined by the external RC network of the tone sequence oscillator and by the ratio of the frequency divider. the relationship between repetition rate $f_{R}$ and oscillator frequency fos is:

$$
f_{R}=\frac{f o s}{3 \cdot 32}
$$

The repetition frequency can be adjusted from $2.4 \mathrm{~Hz} \pm 0.2 \mathrm{~Hz}$ to $25 \mathrm{~Hz} \pm 3.5 \mathrm{~Hz}$ using the connection scheme of Fig. 4 and the following component values:

$$
\begin{aligned}
& \mathrm{C}=4.7 \mathrm{nF} \\
& \mathrm{R} 3=43 \mathrm{~kW} . \\
& \mathrm{R} 4=0 \text { to } 600 \mathrm{~kW}
\end{aligned}
$$

The repetition frequency can be calculated using the formula :

$$
f_{R}(H z)=\frac{10^{6}}{134.4 \cdot C \cdot(20+R)}
$$

with $\mathrm{C}(\mathrm{nF})=$ capacitance between pins 8 and 9 , $R(K \Omega)=$ resitance between pins 8 and 10.
The repetion frequency depends slightly on the supply voltage $V 6-4$. The variation is equal of less than $+4 \%$ per 1 V .

## TONE GENERATOR

The ringing signal is a sequence of three tones. their frequencies are derived from the clock frequency at division rates of 560,420 and 336. Depending of the clock frequency fc the tone frequencies are
$813 \mathrm{~Hz}, 1083 \mathrm{~Hz}, 1354 \mathrm{~Hz}$ for fc $=455 \mathrm{kHz}$ or $800 \mathrm{~Hz}, 1067 \mathrm{~Hz}, 1333 \mathrm{~Hz}$ for fc $=448 \mathrm{kHz}$
This is a harmonic ratio of $3: 4: 5$. the sequence will be started if two conditions are fulfilled : the input ringing signl fin has to be inside a specified frequency band and the supply voltage $\mathrm{V} 6-4$ has to be increased to the turn-on level. The sequence always starts with the lowest tone. The sequence ends, if fin departs from the specified frequency band or if V 6-4 is lowered to the turn-off level.

## TONE OUTPUT

The output amplifier of the SAA1094 tone ringer is a push pull bridge circuit. It supplies two square wave signals of opposite phase at pin 11 and pin 12. The high value of the signal equals the potential of pin 6 and the low value equals the potential of pin 4, if no load is connected to the outputs. Optionally, the pulsewidth of the squarewave output signal can be limited to 0.2 ms internally, in order to save the components of an external limiting circuit containing a capacitor. The shorter pulse-width is of advantage in the case of an electromagnetic transducer being used which will operate with increased efficiency in this case. The connection of pin 13 determines the mode : when connected to pin 4, the pulsewidth is not affected. If pin 13 is left unconnected, the pulsewidth will be 0.2 ms . The waveform of the current through the load is shown for both cases in Fig. 5.

## DIGITAL OUTPUT

The digital output pin 14 can be used for connecting a supplementary load to the supply terminals pins 4 and 6 when the tone generation is deactivated. Without the supplementary load the voltage V 6-4 may decrease significantly upon activation of the tone generation.

The digital output is at the voltage level of pin 6 as long as the two conditions (fin and V 6-4) for the tone generation are not fulfilled. A supplementary load current can then be drawn through an external resistor between pins 14 and 4 . As soon as the conditions for the tone generation are fultilled, the digital output switches to the voltage level of pin 4.

## OVERLOAD PROTECTION

The SAA1094 can withstand an alternating voltage of 110 V at a frequency of 50 Hz across terminals a and $b$ fig. 2 for 15 seconds.
The circuit will not be damaged by a transient voltage test with the following test conditions:
Voltage across the charge capacitor 2 kV
Pulse tinming $\quad 10 / 700 \mu \mathrm{~s}$
Pulse sequence
30 s
Number of transients
16
Polarity change after Test circuit

## TELEPHONE RINGING DETECTOR

## AN AT \& T PRODUCT

- MEETS BOTH TYPE A AND B RINGING REQUIREMENTS ( $40 \mathrm{~V}_{\mathrm{RMS}} \leq \mathrm{VIN} \leq 150 \mathrm{~V}_{\mathrm{RMS}}$, $15 \mathrm{~Hz} \leq \mathrm{F}_{\mathrm{IN}} \leq 68 \mathrm{~Hz}$
- OPERATES ON LESS THAN 1 mA FROM THE TELEPHONE LOOP
- INTERNAL POLARITY GUARD PROVIDES 1500 V LIGHTNING SURGE PROTECTION WHEN CONNECTED AS IN FIG. 11 AND 12
- IMMUNE TO ROTARY DIAL PULSING (BELL TAP)

## DESCRIPTION

The LB1006 provides ringing detection functions from the Tip-ring pair of a telephone loop. This device provides approximately 1 mA output current for two types of output drivers. The output can be connected to either an opto-isolator device or to a logic interface with a microprocessor.

## APPLICATION

The LB1006 detector derives its power by rectifying the $A C$ ringing signal from the Tip-Ring pair of a telephone loop. It operates over widely varying waveforms ( 15 to 68 Hz at 40 to $150 \mathrm{~V}_{\mathrm{RMS}}$ ). It uses this derived power to activate ringing detector logic, and then transfers most of this power to an output current driver. There is essentially no loading under non-ringing conditions. This device has two outputs, OUTH and OUTL. The OUTH output is used to source output current when ringing is detected. The

Figure 7

S-10713

Figure 9

OUTL output will sink output current when the OUTH output is connected to the mirror input and when ringing is detected (see application diagram figure 11 and 12). The device does not have to depend upon power derived from the Tip-Ring inputs to become operational. Connecting an external voltage source to $V+$ will also allow the device to operate in what is described as "Stand Alone Applications".

## DESCRIPTION

TEA7031 is a 28 -pin DIL integrated circuit providing the following facilities:

- Loudspeaker amplifier
- Anti-acoustic feed-back system (anti-Larsen system)
- Microprocessor supply and control
- Switching regulator control

These facilities are generally electrically separated; hence selective use of the functions provided is possible.

## CIRCUIT DESCRIPTION

TEA7031 is a 28 -pin DIL integrated circuit providing the following facilities :

- Loudspeaker amplifier
- Anti-acoustic feed-back system (anti-Larsen system)
- Microprocessor supply and control
- Switching regulator control

These facilities are generally electrically separated; hence selective use of the functions provided is possible.

### 1.1 LOUDSPEAKER AMPLIFIER

The amplifier is divided into 3 main sections :
a) Automatic Gain Control (AGC)
b) Preamplifier
c) Push-pull amplifier (bridge structure).

Figure 9 : Loudspeaker Amplifier.
MBATEATEBI-B2
a) The AGC section is used for the anti-Larsen and anti-distortion system.

- When used in a telephone set to avoid Larsen effect the AGC automatically decreases loudspeaker amplifier gain.
- When the required output level exceeds the capabilities of the available current, the AGC decreases the loudspeaker amplifier gain to avoid distorsion.
b) The preamplifier permits step control of amplifier gain in steps of 6 dB , using pins GAIN ADJ 1 and 2, which may be controlled using switches or by a microprocessor.
The amplifier may be muted using the ON/OFF control signal (pin 26).
c) The output amplifier uses a double push-pull configuration ( H bridge) to get maximum dynamic range under limited supply conditions.

Figure 10 : Output Stage.

## Amplifier DC Supply.

In transmission mode, the supply voltage is controlled by the internal shunt DC regulator. For this reason, the TEA7031 should be supplied from a current
source (see : supply considerations).
An anti-distortion system is embodied which provides AGC control to avoid loudspeaker distortion under current-limited conditions.

Figure 11.

## Circuit action.

When the supply voltage is unsufficient, the voltage at pin 5 , falls below the reference voltage 1.1 V , resulting in transistor (TR) being switched off, resulting in zero current flow in resistor $R$. This state enables the gain control system. Under these conditions, the shunt DC supply will switch at a rate determined by the time constant of the RC network on pin 7.
-This switching action accomodates normal speech characteristics under low supply conditions.

## 1.2 . ANTIACOUSTIC FEEDBACK SYSTEM

 (antilarsen system).The purpose of this system is to control AGC action, in order to avoid acoustic feedback between the loudspeaker and the microphone, when used in a telephone set.

Figure 12.

## Principle of Operation.

When examining, the spectral density of the voice area and the Larsen area, it may be seen that the dominant features of each exist in different frequency bands.

To extract the Larsen component, the microphone signal is first filtered by a second order filter (formed by two first order filters), then amplified and rectified in order to produce the AGC control signal.

Figure 13.

Figure 14.

$\mathrm{i}_{\mathrm{AC}}=\frac{\mathrm{V}_{\text {pin 11 }}}{\mathrm{Z}_{\text {pin 11 }}} \quad$ with $\quad \frac{1}{\mathrm{Z}_{\text {pin 11 }}}=\frac{1}{R 6}+\frac{1}{R 5+\frac{1}{\mathrm{C} 5 \omega}}$
$V_{D C \text { pin } 12}=\frac{\mathrm{i}_{\mathrm{AC}}(\mathrm{RMS}) \cdot 2 \sqrt{2}}{\pi} \mathrm{R} 7$

The first filter is generated by the capacitors on pins 9 and 10 and the input resistor Rin ; the second filter by the RC network on pin 11.
Figure 15.
(Filter on pins 9-10 :

A complete telephone set has two anti-Larsen systems:

- one in the transmission circuit (for example : TEA7050) antisidetone network ;
- one in the loudspeaker amplifier (for example: TEA7031).
Together these form a high efficiency anti-Larsen system.

Figure 16.

### 1.3. MICROPROCESSOR CONTROL.

TEA7031 provides the following signals for an as-
sociated microprocessor :

- halt and reset signal,
- a regulated supply.

The MCU shunt supply voltage is internally fixed at 3.2 V but can be adjusted via pin 15.

Figure 17.

$2 \mathrm{k} \Omega<a<8 \mathrm{k} \Omega$.

Note : Reset and Halt outputs, which are open collector outputs, require external resistors to zero volt.

### 1.4. SWITCHING CONVERTER.

Under ringing conditions the line supply available has a high voltage ( $\sim 22 \mathrm{~V}$ ), low current ( -6 mA ) characteristic. In order to be used by the I.C., this
supply has to be converted to a low voltage ( -3.5 V ) and higher current ( $15-20 \mathrm{~mA}$ ), using a switching converter.

Figure 18.

Transistor T1 is switched either ON/OFF via pin 1 in accordance with the result of a comparison between an internal reference voltage and the I.C. supply voltage (pin 2). When transistor T1 is off, the diode

D2 provides a return current path for L1.
Under speech conditions, the switching converter has to be isolated from the main supply VLS by D1, to prevent reverse current.

Figure 19.
(BASETII

Internal conditions during switching converter operation :

- the internal zener diodes VLS, MCU supply are automatically disconnected,
- the Earphone input is OFF and ringing input is ON .
Note : For better converter efficiency, it is advisable to use schottky diodes for D1 and D2.

## SWITCHING POWER SUPP.LY EFFICIENCY.

## Contribution of external components

Figure 20.

## EQUIVALENT DRAWING :

Efficiency calculation hypotheses :

- lom average output current
- $\mathrm{R}_{\mathrm{L}} . \mathrm{C}_{2}>\mathrm{T} . \mathrm{T}=$ switching period
- Duty cycle $\tau r=\frac{\text { ton }}{T}$
- Be careful that resonance frequency of L.C2 must be lower than switching frequency.

Figure 21.

If $\quad \mathrm{Po}=$ load output power
$\mathrm{Pe}=$ input power
If $\quad$ Ppo $=$ dissipated power in $D 2$ and $L$ Ppe = dissipated power in Q1 and D1
$\mathrm{Po}=\mathrm{Pe}-\mathrm{Ppo}-\mathrm{Ppe}$

& \rho=\frac{V_{o}}{V_{i}}=\frac{V_{i}-\left(V_{D 1}+V_{C E S 1}\right)+V_{D 2}+r o \cdot l O M}{V_{0}+V_{D 2}+r o \cdot l O M}
\end{aligned}
$$

## 2. PIN FUNCTIONS

## PIN 1 : SWITCHING CONVERTER DRIVE

 OUTPUT:Base drive output for the external PNP switching transistor in the switching converter. This switching transistor should have the following characteristics:
$V_{C E O}>30 \mathrm{~V}$; $\mathrm{lc}>200 \mathrm{~mA}$; $\mathrm{G}_{\text {min }}>100$; $\mathrm{fT} \geq 1 \mathrm{MHz}$.

## PIN 2 : SWITCHMODE POWER SUPPLY REGULATION INPUT: <br> This input provides the voltage sensing feedback input to the switching converter. <br> PIN 3 : VZ1 : REF. VOLTAGE TO SWITCHING CONVERTER COMPARATOR:

With pin 4 open circuit, VZ1 is internally stabilized at 3.5 V .

PIN 4 : ADJUST VZ1 :
This pin is used to adjust the switching converter power supply reference voltage.

## PIN 5 : ADJUST VLS :

This pin is used to adjust the I.C. supply voltage.
PINS 6-16-23: GROUND:
These pins have to be connected together.

## PIN 7 : AUTOMATIC GAIN CONTROL FILTER :

The anti-distortion system response is adjusted by the RC network on this pin.

## PIN 8 : CIRCUIT SUPPLY VOLTAGE :

With pin 5 open circuit, VLS is internally stabilized at 2.8 V .
When the TEA7031 is under AGC control, the voltage on this pin varies slightly (due to AGC action).

PIN 9/10 : MICROPHONE INPUTS :
These are used for anti-Larsen control.

## PIN 11 : ANTI-LARSEN FILTER 1

The second filter of the anti-Larsen system ( 1 st filter : pins 9-10) is formed by the RC network R5C5. In order to obtain a second order filter for the antiLarsen system, the cut-off frequency defined at this pin, should be the same as that chosen for the first filter.
For correct TEA7031 operation R6 and R5 should be fixed at $10 \mathrm{k} \Omega$ and $1 \mathrm{k} \Omega$ respectively.

PIN 12 : ANTI-LARSEN FILTER 2 :
The gain and the response of the anti-Larsen system can be adjusted respectively by the resistor and the capacitor on this pin, according to the acoustic characteristics of the telephone set.
The value of the resistor should not exceed $390 \mathrm{k} \Omega$. When the voltage on this pin exceeds the threshold voltage of 0.4 V , the AGC system is enable.

## PIN 13 : EARPHONE INPUT.

Input for loudspeaker signal. This input is only active in transmission mode, but not in ringing mode ; in ringing mode, input pin 19 should be used for amplification of ringing tones. In transmission mode no signal should applied on pin 19, for a proper working of the I.C.

## PIN 14 : MICROPROCESSOR SUPPLY

 VOLTAGE.With pin 15 , open circuit, MCU supply is internally stabilized at 3.3 V , and is available for microprocessor supply purposes.
PIN 15 : MCU SUPPLY ADJUST.
This pin is used to adjust the microprocessor supply voltage.

PIN 17 : MICROPROCESSOR RESET OUTPUT.
This output is an open collector output which delivers a reset signal for a microprocessor.

PIN 18 : MICROPROCESSOR HALT OUTPUT.
This output is an open collector output with delivers a halt signal for a microprocessor.

PIN 19 : SQUARE WAVE RINGING MELODY SIGNAL INPUT.
Input for loudspeaker signal.
This input is only active in ringing mode (when supplied by the switching supply). In transmission mode (when supplied by the shunt DC supply), input 13 should be used and no signal should be applied on pin 19. In ringing mode, it could be used, for example, to generate the microprocessor melody.

PINS 20-22 : LOUDSPEAKER OUTPUTS.
Outputs to be connected to a $50 \Omega$ impedance loudspeaker.
Output voltage : Vpp = 2 VLS-2.5 Volts (with a gain of 32 dB ).
Maximum current : depending of the supply voltage.
PIN 21 : Vref : INTERNAL REFERENCE.
Output which provides an internally regulated reference voltage.
$\mathrm{V}_{\text {ref }}$ : 1.1 V typical.
Maximum available current : $5 \mu \mathrm{~A}$.
PINS 24-25 : GAIN ADJUSTMENT INPUTS.
These pins are used to adjust the loudspeaker amplifier gain. Four steps of $6 \mathrm{~dB} /$ step are available (pin open circuit = high level).

## GAIN ADJUSTEMENT INPUTS

| $\begin{aligned} & \text { GAIN } \\ & \text { ADJ } 0 \end{aligned}$ | $\begin{aligned} & \text { GAIN } \\ & \text { ADJ } 1 \end{aligned}$ | . |
| :---: | :---: | :---: |
| 1 | 1 | $\mathrm{G}_{\text {MAX }}$ |
| 1 | $\varnothing$ | $\mathrm{G}_{\text {MAX }}-6 \mathrm{~dB}$ |
| $\varnothing$ | 1 | $\mathrm{G}_{\text {max }}-12 \mathrm{~dB}$ |
| $\varnothing$ | $\varnothing$ | $\mathrm{G}_{\text {MAX }}-18 \mathrm{~dB}$ |

PIN 26 : LOUDSPEAKER MUTING.
This pin is used to mute the loudspeaker. Pin opencircuit $=$ high level = loudspeaker muted. Pin low level = loudspeaker enabled.

PIN 27 : RING SIGNAL INDICATION.
This NPN open collector output provides ready status when in ringing condition.
DS is ON (low-level) when the switching converter
is established in the running state and when the microprocessor supplies are stabilized. The DS signal is validated by "Halt".
It may be used to cause an associated microprocessor to generate the ringing tones.

PIN 28 : RECTIFIED RING SIGNAL INPUT.
High voltage input for the switching converter.
Maximum voltage : 22 V .

## 3. SUPPLY CONSIDERATIONS

### 3.1. SWITCHING SUPPLY LAY-OUT.

To avoid switching-noise, C2, C3, D2 should be tied together as close as possible.
Figure 23.

## 3.2 . TEA7031 SUPPLY.

As the I.C. has a zener characteristic, it should be supplied by a current source.
Constant voltage supply :
The TEA7031 can be supplied by an external constant voltage on condition :

To set the zener voltages at a level higher than the supply voltage.
To tie the automatic gain control pin (pin 7) to the ground (otherwise the I.C. will always be in AGC mode).
Note : The maximum loudspeaker level is depending of the supply voltage.

Figure 24 : Typical Application.

## MONITOR AMPLIFIER

## FUNCTIONAL DESCRIPTION

TEA7531 performs the following functions :
The circuit amplifies the incoming signal and feeds it to the loudspeaker. PG0 and PG1 inputs are used to set the loudspeaker gain in a range of 32dB to 14dB in 6dB steps.
The TEA7531 inputs (PG0, PG1, ON/OFF) permit the loudspeaker to be cut-off thus ensuring privacy of communication.

- The antilarsen (antiacoustic feedback) system is incorporated.
- The maximum power available on a 50 ohms impedance loudspeaker is 25 mW at 3 volts and 100 mW at 5 volts.
Limit values for external components :
R3 min $=5$ kohms (R3 adjust VLS).
R7 max $=390$ kohms.
R6 $\min =R 7 / 35$.
$R$ max between pin 5 and $6=10$ kohms $+C$ min $=$ 10nf.

ELECTRICAL CHARACTERISTICS : $\left(\mathrm{T}_{\mathrm{amb}}=25^{\circ} \mathrm{C}, \mathrm{I}_{\mathrm{LS}}=30 \mathrm{~mA}\right.$ unless otherwise specified)

## CIRCUIT DESCRIPTION

TEA7531 is a 16 pin DIL integrated circuit providing the following facilities :

- Loudspeaker amplifier.
- Antiacoustic feed-back system (antilarsen system).

### 1.1. LOUDSPEAKER AMPLIFIER.

Figure 10.
EARPHONE INPUT M89TEAT531-13

The amplifier is divided into 3 main sections.

- Automatic Gain Control (AGC)
- Preamplifier
- Push-pull amplifier (bridge structure)
a) The AGC section is used for the antilarsen and antidistortion system.
- When used in a telephone set to avoid larsen effect the AGC automatically decreases loudspeaker amplifier gain.
- When the required output level exceeds the capabilities of the available current, the AGC decreases the loudspeaker amplifier gain to avoid distortion.
b) The preamplifier permits step control of amplifier gain in steps of 6 dB , using pins PG0 and PG1, which may be controlled using switches or by a microprocessor. The amplifier may be muted using the ON/OFF control signal (pin 16).
c) The output amplifier uses a double push-pull configuration ( H bridge) to get maximum dynamic range under limited supply conditions.

Figure 11.

## Amplifier dc supply.

In transmission mode, the supply voltage is controlled by the internal shunt DC regulator. For this reason, the TEA7531 should be supplied from a current source.
(see : supply considerations).
An antidistortion system is embodied which provides AGC control to avoid loudspeaker distortion under current-limited conditions.

Figure 12.

## Circuit action.

When the supply voltage is insufficient, the voltage at pin 1 , falls below the reference voltage 1.1 V , resulting in transistor (TR) being switched off, resulting in zero current flow in resistor R. This state enables the gain control system. Under these conditions, the shunt DC supply will switch at a rate determined by the time constant of the RC network on pin 3.

This switching action accomodates normal speech characteristics under low supply conditions.

### 1.2. ANTIACOUSTIC FEED-BACK SYSTEM (antilarsen system)

The purpose of this system is to control AGC action in order to avoid acoustic feed-back between the loudspeaker and the microphone, when used in a telephone set.

Figure 13.

## Principle of operation.

When examining the spectral density of the voice area and the larsen area, it can be seen that the do-
minant features of each exist in different frequency bands.

Figure 14.

To extract the larsen component, the microphone signal is first filtered by a second order filter (formed
by two first order filters), then amplified and rectified in order to produce the AGC control signal.

Figure 15.

The first filter is generated by the capacitors on pins 5 and 6 ; the second filter by the R-C network on pin 7.

Figure 16 : Antilarsen System Filter Response.

Filter on pins 5 \& 6
$\mathrm{f} 2=\frac{\mathrm{C} 9+\mathrm{C} 10}{2 \pi \mathrm{ZinC9C10}}$

Filer on pin 7
$\mathrm{f} 1=\frac{1}{2 \pi(\mathrm{R} 5+\mathrm{R} 6) \mathrm{C} 5}$
$\mathrm{f} 3=\frac{1}{2 \pi \mathrm{R} 5 \mathrm{C} 5}$

Antilarsen system
Filter response

If $\mathfrak{f 2}=\mathrm{f} 3$ the Antilarsen system filter is equivalent to a second order filter.

$$
\frac{\mathrm{C} 9+\mathrm{C} 10}{2 \pi \mathrm{Zin} \mathrm{C} 9 \mathrm{C} 10}=\frac{1}{2 \pi \mathrm{R} 5 \mathrm{C} 5}
$$

A complete telephone set has two antilarsen systems:

- one in the transmission circuit (for example : TEA7051) antisidetone network ;
- one in the loudspeaker amplifier (for example : TEA7531).
Together these form a high efficiency antilarsen system.

Figure 17.

## PIN FUNCTIONS

PIN 1 : ADJUST VLS
This pin is used to adjust the IC supply voltage.
PINS 2-13 Ground :
These pins have to be connected together.

PIN 3 : AUTOMATIC GAIN CONTROL FILTER
The antidistortion system response is adjusted by the R-C network on this pin.
The AGC will be switched ON when the level on pin 3 is greater than the reference voltage ( 0.4 V ), the RCnetwork charges (current source ON) or discharges (current source OFF) according to the supply voltage.

## THEORETICAL VOLTAGE ON PIN 3

Figure 18.

- The value of $R$ affects the system time constant and the charge/discharge duty cycle.
- R should be greater or equal than $150 \mathrm{k} \Omega$ for correct AGC operation.
- The value of $C$ only affects the system time constant.

Figure 19.

PIN 4 : CIRCUIT SUPPLY VOLTAGE
With pin 1 open circuit, VLS is internally stabilized at 2.8 V .

When the TEA7531 is under AGC control, the voltage on this pin varies slightly (due to AGC action).

## PIN 5/6 : MICROPHONE INPUTS

These are used for antilarsen control.

## PIN 7 : ANTILARSEN FILTER 1

The second filter of the antilarsen system (1 st filter : pins 5-6) is formed by the RC network R5C5. In order to obtain a second order filter for the antilarsen system, the cut-off frequency defined at this pin, should be the same as that chosen for the first filter.
For correct TEA7531 operation R6 and R5 should be fixed at $10 \mathrm{k} \Omega$ and $1 \mathrm{k} \Omega$ respectively.

## PIN 8 : ANTILARSEN FILTER 2

The gain and the response of the antilarsen system can be adjusted respectively by the resistor and the capacitor on this pin, according to the acoustic characteristics of the telephone set.
The value of the resistor should not exceed $390 \mathrm{k} \Omega$. When the voltage on this pin exceeds the threshold voltage of 0.4 V , the AGC system is enabled.

## PIN 9 : EARPHONE INPUT

Input for loudspeaker signal.

## PIN 10-12 : LOUDSPEAKER OUTPUTS

Maximum output voltage : $\mathrm{V}_{\mathrm{pp}}=2 \mathrm{~V} \mathrm{Ls}-2.5 \mathrm{~V}$ (with a gain of 32 dB ).
Maximum output current : depending of the supply current.

Figure 20.

Two loudspeaker connection methods are possible, using the amplifier in either " H " mode or " B " mode.
Note : It is advisable to connect a 47nF capacitor in parallel with the loudspeaker (between pins 10 and 12).

## - "H" Mode

This is for low voltage working, but at a higher supply current. The highest output power is available in this mode, due to the 5.5 V maximum supply voltage restriction, imposed by the TEA7531.
Loudspeaker impedance recommended value : $50 \Omega$.
Maximum gain available between earphone input and loudspeaker output: 32dB.

## - "B" Mode

This allows higher voltage operation, but at a lower supply current.
Loudspeaker impedance recommended value : $25 \Omega$.
Maximum gain available between earphone input and loudspeaker output : 32-6 = 26dB.

PIN 11 : Vref : INTERNAL REFERENCE
Output which provides an internally regulated reference voltage.
$V_{\text {ref }}=1.1 \mathrm{~V}$ typical
MAXIMUM AVAILABLE CURRENT : $5 \mu \mathrm{~A}$.
Figure 21.

## PIN 14-15 : GAIN ADJUSTMENT INPUTS

Figure 22.

PIN 16 : LOUDSPEAKER MUTING.

| PG0 | PG1 |  |
| :---: | :---: | :--- |
| 1 | 1 | Gmax |
| 1 | 0 | Gmax -6 dB |
| 0 | 1 | Gmax -12 dB |
| 0 | 0 | Gmax -18 dB |

These pins are used to adjust the loudspeaker.
Pin open circuit : high level = loudspeaker muted.
Pin low level: loudspeaker enabled.
See connection of Pins 14 and 15.

## MONITOR AMPLIFIER

- PROGRAMMABLE GAIN INSTEPSOF6dBOR LINEARLY
- ON/OFF POSITION
- LOW VOLTAGE
- POWER : 100 mW AT 5 V

This 16 pins IC is designed for monitor
(loudspeaker) telephone set and provides:
a) Signal amplification for monitoring (loudspeaker)
b) Antiacoustic feedback (antilarsen)
c) Antidistortion by automatic gain adaptation
d) Antilarsen adjustment (full duplex)

## FUNCTIONAL DESCRIPTION

TEA7532 performs the following functions :
The circuit amplifies the incoming signal and feeds it to the loudspeaker. PG0 and PG1 inputs are used to set the loudspeaker gain in a range of 32 dB to 14 dB in 6 dB steps.
The TEA7532 inputs (PG0, PG1, ON/OFF) permit the loudspeaker to be cut-off thus ensuring privacy of communication.

- The antilarsen (antiacoustic feedback) system is incorporated.
- The maximum power available on a 50 ohms impedance loudspeaker is 25 mW at 3 volts and 100 mW at 5 volts.

Limit values for external components :
R3 min $=5$ kohms (R3 adjust VLS)
R7 max $=390$ kohms
$R 6$ min $=R 7 / 35$
$R$ max between pin 5 and $6=10$ kohms $+C$ min $=$ 10 nF .

ELECTRICAL CHARACTERISTICS : $\left(T_{\mathrm{amb}}=25^{\circ} \mathrm{C}, \mathrm{I}_{\mathrm{Ls}}=30 \mathrm{~mA}\right.$ unless otherwise Specified)

## CIRCUIT DESCRIPTION

TEA7532 is a 16 pin DIL integrated circuit providing the following facilities :

- Loudspeaker amplifier
- Antiacoustic feed-back system (antilarsen system)

### 1.1. LOUDSPEAKER AMPLIFIER

Figure 11.

The amplifier is divided into 3 main sections.

- Automatic Gain Control (AGC)
- Preamplifier
- Push-pull amplifier (bridge structure)
a) The AGC section is used for the antilarsen and antidistortion system.
- When used in a telephone set to avoid larsen effect the AGC automatically decreases loudspeaker amplifier gain.
- When the required output level exceeds the capabilities of the available current, the AGC
decreases the loudspeaker amplifier gain to avoid distortion.
b) The preamplifier permits step control of amplifier gain in steps of 6 dB , using pins PG0 and PG1, which may be controlled using switches or by a microprocessor. The amplifier may be muted using the ON/OFF control signal (pin 16).
c) The output amplifier uses a double push-pull configuration ( H bridge) to get maximum dynamic range under limited supply conditions.

Figure 12.

## Amplifier dc supply.

In transmission mode, the supply voltage is controlled by the internal shunt DC regulator. For this reason, the TEA7532 should be supplied from a current source
(see : supply considerations).
An antidistortion system is embodied which provides AGC control to avoid loudspeaker distortion under current-limited conditions.

Figure 13.

## Circuit action.

When the supply voltage is insufficient, the voltage at pin 1 , falls below the reference voltage 1.1 V , resulting in transistor (TR) being switched off, resulting in zero current flow in resistor R. This state enables the gain control system. Under these conditions, the shunt DC supply will switch at a rate determined by the time constant of the RC network on pin 3.

This switching action accomodates normal speech characteristics under low supply conditions.
1.2. ANTIACOUSTIC FEED-BACK SYSTEM (ANTILARSEN SYSTEM)
The purpose of this system is to control AGC action in order to avoid acoustic feed-back between the loudspeaker and the microphone, when used in a telephone set.

Figure 14.

Principle of operation.
When examining the spectral density of the voice area and the larsen area, it can be seen that the do-
minant features of each exist in different frequency bands.

Figure 15.

To extract the larsen component, the microphone signal is first filtered by a second order filter (formed
by two first order filters), then amplified and rectified in order to produce the AGC control signal.

Figure 16.

The first filter is generated by the capacitors on pins 5 and 6 ; the second filter by the R-C network on pin 7.

Figure 17 : Antilarsen System Filter Response.

A complete telephone set has two antilarsen systems:

- one in the transmission circuit (for example : TEA7051) antisidetone network ;
- one in the loudspeaker amplifier
(for example : TEA7532).
Together these form a high efficiency antilarsen system.

Figure 18.

## PIN FUNCTIONS

## PIN 1 : ADJUST VLs

This pin is used to adjust the IC supply voltage.
PIN 2 : ANTILARSEN ADJUSTMENT
The AC signal at this pin is amplified to the loudspeaker without AGC attenuation.

PIN 3 : AUTOMATIC GAIN CONTROL FILTER
The antidistortion system response is adjusted by the R-C network on this pin.
The AGC will be switched ON when the level on pin 3 is greater than the reference voltage ( 0.4 V ), the RCnetwork charges (current source ON) or discharges (current source OFF) according to the supply voltage.

## THEORETICAL VOLTAGE ON PIN 3

Figure 19 :

- The value of $R$ affects the system time constant and the charge/discharge duty cycle.
- The value of C only affects the system time constant.
- R should be greater or equal than $150 \mathrm{k} \Omega$ for correct AGC operation.
Figure 20.
Speech

PIN 4 : CIRCUIT SUPPLY VOLTAGE
With pin 1 open circuit, VLS is internally stabilized at 2.8 V .

When the TEA7532 is under AGC control, the voltage on this pin varies slightly (due to AGC action).

## PIN 5/6 : MICROPHONE INPUTS

These are used for antilarsen control.

## PIN 7 : ANTILARSEN FILTER 1

The second filter of the antilarsen system ( 1 st filter : pins 5-6) is formed by the RC network R5C5.
In order to obtain a second order filter for the antilarsen system, the cut-off frequency defined at this pin, should be the same as that chosen for the first filter.

For correct TEA7532 operation R6 and R5 should be fixed at $10 \mathrm{k} \Omega$ and $1 \mathrm{k} \Omega$ respectively.

## PIN 8 : ANTILARSEN FILTER 2

The gain and the response of the antilarsen system can be adjusted respectively by the resistor and the capacitor on this pin, according to the acoustic characteristics of the telephone set.
The value of the resistor should not exceed $390 \mathrm{k} \Omega$. When the voltage on this pin exceeds the threshold voltage of 0.4 V , the AGC system is enabled.

PIN 9 : EARPHONE.INPUT
Input for loudspeaker signal.

## PIN 10-12 : LOUDSPEAKER OUTPUTS

Maximum output voltage: $\mathrm{V}_{\mathrm{pp}}=2 \mathrm{~V} \mathrm{LS}-2.5 \mathrm{~V}$ (with a gain of 32 dB ).
Maximum output current : depending of the supply current.
Two loudspeaker connection methods are possible, using the amplifier in either " H " mode or " B " mode.
Note : It is advisable to connect a 47 nF capacitor in parallel with the loudspeaker (between pins 10 and 12).

## - "H" Mode

This is for low voltage working, but at a higher supply current. The highest output power is available in this mode, due to the 5.5 V maximum supply voltage restriction, imposed by the TEA7532.
Loudspeaker impedance recommended value: $50 \Omega$. Maximum gain available between earphone input and loudspeaker output: 32 dB .

Figure 21.

Figure 22.

- "B" Mode

This allows higher voltage operation, but at a lower supply current.
Loudspeaker impedance recommended value: $25 \Omega$. Maximum gain available between earphone input and loudspeaker output : 32-6 = 26 dB .

PIN 11 : Vref : INTERNAL REFERENCE Output which provides an internally regulated reference voltage.
Vref $=1.1 \mathrm{~V}$ typical

## FUNCTIONAL DESCRIPTION

## SWITCHED ATTENUATORS

Fig. 1 represents a block diagram of a handsfree subset with attenuators in signal mode. To prevent the system from howling, the total loop gain, including acoustic feedback through the housing and sidetone coupling, must be less than OdB. For this purpose, two switched attenuators are inserted in each mode (emission and reception). The attenua-
tion is shifted from one mode to the other, resulting from the speech level comparison between each way.
To prevent the circuit to switch continuously in one way, the operation of the IC must be fully symetrical in both ways. This involves signal comparison, attenuation value.

Figure 1.

## GAIN COMPRESSORS

In TEA7540, two signal compressors are inserted in each mode before the signal comparison, so the signal coming from each end has the same level ( 100 mV peak), the losses in each way (for instance losses resulting from the line lenght in receiving mode) are compensated and the signal comparison is fully symetrical. The time constant of each signal compressor is fixed by an external capacitor, but the gain of the compressor decreases 100 times more quickly than it increases to prevent from noise increasing between words. The compressing depth is 38dB.

## BACKGROUND NOISE DISCRIMINATION

An additional feature provided in TEA7540 is background noise level discrimination in each way. The IC stores the background sound level with a long time constant ( 3 to 5 seconds depending on an external RC) and compares it with the incoming signal in order to distinguish a usefull signal (speech)
from the background noise. This background noise memorisation is also used to compensate the noise in each mode before signal comparison : the noise level in each mode is substracted from the incoming signal before the comparison. So a very high noise level in one mode cannot trouble the comparison between the usefull signals.
The result of the comparison manages the attenuators in the following way :

- The maximum attenuation is switched on the mode where the speech signal is the lowest. The maximum attenuation is fixed by two external resistors (maximum 52dB). The time constant of the switch is fixed by the timer via an external capacitor.
- When neither party is talking both attenuators are set to a medium attenuation. Thus each mode is in idle mode. The time constant of the switch from active mode to idle mode must be long enough to prevent from switching to idle mode between two words (see fig 2). This time constant is fixed by an external RC.

Figure 2.

## TEA7540 OPERATION

TEA7540 is powered through an external shunt regulator (for instance the shunt regulator of the monitor amplifier TEA7531) or an external zener diode. It can work at a very low voltage ( 2.5 volts ) over the circuit and it has a low current consumption ( 2.1 mA ). It's also possible via the chip select pin (CS) to put
the handsfree function in standby to use the circuit in monitoring mode with the handset microphone.
TEA7540 is designed to work with all kinds of microphones, including Electret.
TEA7540 also handles the handset microphone signal (AMP2) when the system is set to normal conversation mode (AMP1).

Figure 3 : Application Diagram.
Example of high range telephone set using TEA7540.

## SPECIAL FUNCTIONS

## MICROPHONE AMPLIFIER

- VERY FEW EXTERNAL COMPONENTS
- BUILT IN PARTIAL BRIDGE
- HIGH IMMUNITY AGAINST EMI
- ACCURATE GAIN CONTROL
- NO CAPACITOR REQUIRED
- WIDE OPERATING VOLTAGE AND CURRENT RANGE
- PROGRAMMABLE DC CHARACTERISTICS

## DESCRIPTION

The LS188 is a monolithic microphone amplifier designed to be used with several kinds of transducers. It can replace the carbon microphone in telephones and may also be used in cassette recorder, walky talkies, or infrared receiver applications. The circuit is assembled in a 8-pin Dual in Line Package. The LS188 consists of a differential input amplifier,
internal reference and a current modulator stage enabling the device to send the amplifier speech to the line.

- MEETS DC LINE CHARACTERISTICS OF EITHER CCITT AND EIA RS 464 SPECS
- PULSE FUNCTION
- HIGH AC IMPEDANCE
- OFF HOOK-STATUS DETECTION OUTPUT
- LOW EXTERNAL COMPONENT COUNT

## DESCRIPTION

The circuit provides DC loop termination for analog trunk lines.

The V-I characteristics is equivalent to a fixed voltage drop (zener like characteristic) in series with an external resistance that determines the slope of the DC characteristic.
An external low voltage electrolytic capacitor causes the circuit to exhibit a very high impedance to all AC signal above a minimum frequency that is determined by the capacitor itself and by a 20 K nominal resistor integrated on the chip.
The Off-Hook status is detected all the time a typic of 8 mA is flowing into the circuit. In this condition a constant current generator is activated to supply an external device (typically an optocoupler) without affecting the AC characteristic of the circuit.
When Pulse Dialing is required the PULSE input (pin 3) connected to $V$-causes the device to reduce the fixed DC voltage drop and to exhibit a pure resistive impedance equal to the external resistor.

## APPLICATION INFORMATION

With the use of this circuit it is possible to terminate an analog trunk so that all the DC current component is flowing in the TRUNK TERMINATION CIRCUIT while the AC component is decoupled with a low voltage capacitor and can be used with a small and low cost audio coupler transformer to provide the $A C$ balancing termination and two to four wire conversion.
Therefore it is usefull both for MODEM and PABX systems.

Figure 1 gives the typical application circuit ; it is worth to note that the TRUNK TERMINATION CIRCUIT, together with the LS5018 transient suppressor provides a compact and low cost module fully protected against lightning or overvoltages frequently present on telephone lines.
The PULSE input when connected to V - allows the device to reduce the Line Voltage and to show a resistive impedance equal to R1 to the line. When PULSE input is left open, this function is disable.

Figure 1 : Typical Application.

## LINE INTERFACE

Designed to interface an equipment with the telephone line, this 8 pin IC provides:

- LINE ADAPTATION
- RING DETECTION

It is particularly convenient for modem applications and fulfills a wide range of international specifications.
Line adaptation : (DC characteristics)

- ZENER CHARACTERISTIC WITH ADJUSTABLE SLOPE
- ADJUSTABLE DYNAMIC IMPEDANCE
- ADJUSTABLE MAXIMUM AMPLITUDE OFTHE SIGNAL
- USE ONLY A LOW COST DRY TRANSFORMER
- NEED NO DIALLING RELAY

Ring detection :

- ADJUSTABLE DETECTION LEVEL
- ADJUSTABLE AC IMPEDANCE
- VERY LOW LINE DISTORTION

## BLOCK DIAGRAM

## - LOGIC SIGNAL OUTPUT

Other:

RING DETECTOR

| Name | $\mathbf{N}^{\circ}$. | Description |
| :---: | :---: | :--- |
| $V_{R}$ | 5 | Ring detection output connected to an optocoupling device. |
| $R_{S}$ | 6 | $R_{S}$ fixes the ring detection level. |
| $R_{D}$ | 7 | Ring Detection Input. $R_{D}$ fixes the impedance of the ring detector. |

## OUTLINES

Specially designed for the modem applications, this 8 pins IC provides line adaptation, ring detection and easy pulse dialling. It is a Direct Connect Circuit (DCC) which has been designed to fulfill a wide range of $A C$ and $D C$ specifications for various countries.

## RING DETECTION

This circuit detects the incoming ringing signal and generates a logic signal to the microcomputervia an optocoupling device. The detection level can be fixed by an external resistor. The dynamic impedance of the ring detector is also fixed by an external resistor. The line distortion of the ringing signal is very low compared to the distortion introduced by a zener detector.

## LINE ADAPTATION

The DC characteristic can fulfill a wide range of DC specifications:

- zener characteristic with adjustable slope fixed by an external resistor
- line current limitation using an external CTP.

The dynamic impedance is fixed by an external resistor Rvst so as to match with different line impedances.
The maximum amplitude of the signal is fixed by two external resistors Rvst and Rc.
This circuit has been designed to be connected to a low cost dry transformer.
The application has been studied to avoid the use of dialling relay.
With its possibility of ring detection, off-hook are dialling this circuit is adapted to the application in smart modems. It also satisfies the FCC Rules Part 68.

SGS-THOMSON

## APPLICATIONS INFORMATION

Figure 5 : Ring Detection.

The ringing signal coming from the line is rectified by the diode bridge ; the circuit compares the peak amplitude of the signal to a predeterminated detection level fixed by Rs. On the output transistor of the optocoupling device a logic signal is generated which frequency is twice the frequency of the ringing signal.
" 0 " = the amplitude of the ringing signal is greater than the detection level.
"1" = the amplitude of the ringing signal is lower than the detection level.
The ring detection circuit is fully linear ; so the distortion on the line is very low compared to the distorsion introduced by a zener detector as usually used.
Three external components affect the characteristic of the ring detection circuit. The capacitor $\mathrm{C}_{\mathrm{R}}$ provides the DC solation from the line.
The AC impedance of the circuit at the ringing frequency is given by the formula :

$$
Z_{A C}=Z_{C R}(f)+R_{D}+R_{S} / 13
$$

$Z_{C R}$ is the impedance of the capacitor $C_{R}$ at the ringing frequency.
The ring detection level is fixed by the external resistor Rs with the following formula:

$$
R_{S}=\frac{11 \text { volts }}{V_{R}-V_{D}-3 \text { volts }} R_{D}
$$

$V_{R}$ is the peak amplitude of the ringing signal at the detection level.
$V_{D}$ is the voltage over the diode bridge and the capacitor $C_{R}$ at the ringing frequency.

The DC characteristic is a zener characteristic which slope is fixed by $\mathrm{R}_{\mathrm{M}}$ (see fig.8). The voltage over the circuit (pin 1) is fixed via a current source driven through Rvst. The value of this current source is fixed by the external resistor Rc with the formula:

$$
\mathrm{V}(\text { Rvsi })=\mathrm{V}(\text { pin1 })-\mathrm{V}(\text { pin2 })=\frac{R \mathrm{VsI}}{R_{c}} \times 2.46 \text { volts }
$$

Note that the voltage through Rvst also limits the amplitude of the emitted signal.
The external resistor Rvst also defines the AC impedance of the circuit:
$Z_{A C}=$ Rvst / / impedance seen from the transformer (see hybrid system)

* When a current limitation is required for the DC characteristic (as for the French specification), an external TPE is connected between the telephone line and the circuit (see application diagram).

## PULSE DIALLING

Pulse dialling is easily done using a high voltage optocoupling device and a high voltage PNP transistor as shown on the typical application diagram.

## HYBRID SYSTEM

This system uses an operational amplifier to prevent from injecting the emitted signal in the receiving path of the modem IC. A typical diagram is given at fig. 9.

RL represents the impedance of the telephone line $Z_{L}$ in parallel with Rvst. Typically we take $Z_{L}=600$ ohms.

Figure 6 : AC/DC Line Adaptation.

Figure 7 : This part of the TEA7868 is used for line adaptation.

Figure 8 : An Equivalent Diagram of the Circuit is given at fig. 7.

The hybrid gain of the system is given by :
$G D=\frac{V_{s}}{V_{E}}=1-\frac{R_{2}+R_{3}}{R_{2}} \frac{R_{1}}{R_{1}+R_{L}}$
For a maximum efficiency you must have $\mathrm{GD}_{\mathrm{D}}=0$ and this gives:
$\frac{R_{3}}{R_{2}}=\frac{R_{L}}{R_{1}}$
The impedance seen from the line must be 600 ohms, this impedance is given by :
$Z_{\text {out }}=\mathrm{R}_{1} / /$ Rvst
So, if Rvst is fixed, $R_{1}$ is also fixed by $Z_{\text {out }}=600$ ohms.

The gain between the online signal and the modem input is :
$G_{E}=\frac{R_{L}}{R_{1}+R_{L}}$
The gain between the line and the modem input is:
$G_{R}=1+\frac{R_{3}}{R_{2}}$
Those calculations are purely theoretical ; really the line impedance has a complex component, so there will be little changes in the value of $R_{1}, R_{2}, R_{3}$ to adapt the hybrid system.

## APPLICATION

The LH1028 device can be connected in the following manner to perform telephone interface functions. An overvoltage metal-oxide-varistor or other similar type of device shunts the Tip-Ring input terminal of the LH1028 TIC and limits the voltage across these terminals to less than 200 V (the maximum voltage rating of the LH1028). The output terminals of the LH1028 TIC are TPRIME ( $T^{\prime}$ ) and

RPRIME ( $\mathrm{R}^{\prime}$ ). T' and R' are the positive and negative sides of the TIC polarity guard, respectively. R' is connected to the telephone circuitry through a switch which is internal to the LH1028 TIC. This internal switch opens when a dial pulse voltageis applied between terminal DP (Dial Pulse) and DP' (Dial Pulse Prime).

Figure 9 : Typical Telephone Set Configurations.

## SINGLE POLE HIGH-VOLTAGE SOLID-STATE RELAY

- HIGH VOLTAGE IC FABRICATED IN A DIELECTRIC ISOLATION PROCESS
- OPTICAL COUPLING BETWEEN INPUT AND OUTPUT
- CAN SWITCH LOADS UP TO 350V AT CURRENTS UP TO 100mA
- LOW ON-RESISTANCE
- CLEAN, BOUNCE-FREE SWITCHING
- HIGH CURRENT SURGE CAPABILITY
- LOW-POWER CONSUMPTION
- NO ELECTROMAGNETIC INTERFERENCE

## DESCRIPTION

The LH1056 (Multipurpose Solid-State Relay) is a low-cost, bi-directional, SPST designed to switch both AC and DC loads. Output is rated at 350 volts and can handle loads up to 100 mA . It is packaged in a special 6-pin plastic DIP.
Each device consists of one GaAIAs LED to optically couple the control signal to a high-voltage integrated circuit. The typical ON-Resistance is 30 ohms at

AN AT \&T PRODUCT

25 mA , and is exceptionally linear up to 50 mA . Beyond 50 mA , the incremental resistance becomes even less, thereby minimizing internal power dissipation. The LH1056 also has internal current limiting which clamps the load current at 150 mA to insure that the device will survive during current surges.

Figure 1 : Functional and Equivalent Relay Diagrams.

PIN CONNECTION (top view)

## PIN DESCRIPTION

| Name | Description |
| :---: | :--- |
| Control + <br> Control - | These pins are the positive and negative inputs respectively to the input control LED. An <br> appropriate amount of current through the LED will close the circuit path between S and S'. |
| S-S' | These pins are the outputs. The pin pair S-S' represents one normally open relay pole. |
| Blank | This pin may be used as a tie-point for external components. Voltage on this pin should not <br> exceed 300V. |
| NC | This pin is connected to internal circuitry. It should not be used as a tie-point for external <br> circuitry. |

ABSOLUTE MAXIMUM RATINGS (at $25^{\circ} \mathrm{C}$ unless otherwise specified)

## INPUT/OUTPUT ISOLATION

The optical coupling between input and output provides a great degree of isolation between the lowvoltage control and the high voltage output. Each device meets the $1500 \mathrm{Vrms} \mathrm{U} / \mathrm{L}$ (Underwriters Laboratories) test, which requires the product to withstand 1500 Vrms for a time of one minute. For throughput purposes, U/L allows reduction of the test time to 1 second if the stress is increased to 1800 Vrms.

In order to further assure long term reliability, each device is tested with an additional 600 Vrms of guardband, bringing the total test stress to 2400 Vrms for one second. During the test, less than 100 nA of leakage is required. After passing this test, the part is subjected to the parameters specified by the data sheet.

## LOAD PROTECTION

The LH1056 has been designed to protect the switching load by quick transient suppression and by output current limitation. These features can be illustrated by evaluation of the step response of the closed contact.
The circuit used for evaluation is shown in figure 12. First, a control signal is applied in order to activate the switch.' Then transistor TR1 is turned on, which activates a 50 V step through $100 \Omega$ across the closed switch. The switch reacts.to the leading edge of the step by quickly deactivating, stopping current flow in the load. The resultant load current is shown in figure 13. After $250 \mu \mathrm{~s}$, the switch recloses, allowing current to flow in the load, up to the current limit of the device, if necessary. This clamping can be seen in figure 14 which also shows the fast shutoff at the leading edge of the step.

## APPLICATION

This device has been optimized to meet the demands of switching high voltages at moderate current levels in applications such as telecommunications, instrumentation, and medium-power switching. It is ideally suited for applications where high performance, noise-free switching of ac and dc signals is desirable.
The operational range of this device includes lowpower commercial voltage applications where millampere control signals and low ON-resistance are required. The speed, reliability, and linearity of this switch makes it well suited for those applications which are beyond the range of mechanical relays, thyristors, and triacs. For lower ON resistance, hi-

$X=0.2 \mathrm{~ms} / \mathrm{div}$.
$Y=40 \mathrm{~mA} / \mathrm{div}$.
Upper Trace : command pulse.
Lower Trace : load current.

gher voltages, or greater current capability, the LH1056 can be easily combined in parallel or series arrangements, as required, with their control LEDs simply driven in series.
The low ON-resistance and low-noise features are beneficial in instrumentation applications. The optical coupling provides isolation of the switch from the control signal in high-voltage and high-frequency applications.
The fabrication of high-voltage, monolithic ICs in a unique dielectric isolation process provides high reliability and the solid-state construction eliminates problems associated with mechanical relays such as sensitivity to shock and vibration.

## DOUBLE POLE HIGH-VOLTAGE SOLID-STATE RELAY

## AN AT \& T PRODUCT

- HIGH VOLTAGE IC FABRICATED IN A DIELECTRIC ISOLATION PROCESS
- OPTICAL COUPLING BETWEEN INPUT AND OUTPUT
- CAN SWITCH TWO SEPARATE LOADS UP TO 200V EACH AT CURRENTS UP TO 200mA
- LOW ON-RESISTANCE
- CLEAN, BOUNCE-FREE SWITCHING
- HIGH CURRENT SURGE CAPABILITY
- LOW-POWER CONSUMPTION
- NO ELECTROMAGNETIC INTERFERENCE

## DESCRIPTION

The LH1061 (Multipurpose Solid-State Relay) is a low-cost, bi-directional, SPDT designed to switch both AC and DC loads. Outputs are rated at 200 V and can handle contemporarily two loads up to 200 mA . It is packaged in a special 8-pin plastic DIP.
Each device consists of one GaAIAs LED to optically couple the control signal to two high-voltage integrated switches. The typical ON-Resistance is $15 \Omega$ at 25 mA , and is exceptionally linear up to 100 mA . Beyond 100 mA , the incremental resistance becomes even less, thereby minimizing internal power dissipation. The LH1061 also has internal current limiting which clamps the load current at 300 mA to insure that the device will survive during current surges.

## PIN DESCRIPTION

| Name | Description |
| :---: | :--- |
| Control + <br> Control - | These pins are the positive and negative inputs respectively to the input control LED. An <br> appropriate amount of current through the LED will close the circuit path between S and S'. |
| S1, S1' <br> S2, S2' | These pins are the outputs. The pins designated as $S$ represents one side of a relay pole. The <br> pins designated as $S^{\prime}$ are the complementary side of a relay pole. Note that $S 2$ is connected to <br> the substrate. |
| NC | This pin is connected internally for test purposes. It should NOT be used as a tie-point for <br> external components. |
| Blank | This pin may be used as a tie point for external components. Voltage applied to this pin should <br> no exceed 150V. |

ABSOLUTE MAXIMUM RATINGS (at $25^{\circ} \mathrm{C}$ unless otherwise specified)

| Parameter | Value | Unit |
| :--- | :---: | :---: |
| Ambient Operating Temperature Range | -40 to +85 | ${ }^{\circ} \mathrm{C}$ |
| Storage Temperature Range | -40 to +100 | ${ }^{\circ} \mathrm{C}$ |
| Pin Soldering Temperature ( $\mathrm{t}=15 \mathrm{~s}$ max) | 300 | ${ }^{\circ} \mathrm{C}$ |
| LED INPUT : |  |  |
| Continuous Forward Current | 20 | mA |
| Reverse Voltage | 10 | V |
| Operating Voltage | 200 | V |
| One Pole (S1, S1' or S2, S2') | 300 | mA |
| Each Pole (two poles operating simultaneously) | 200 | mA |

Stresses in excess of those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions in excess of those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## OP-AMPs COMPARATORS

## HIGH PERFORMANCE DUAL OPERATIONAL AMPLIFIER

- SINGLE OR SPLIT SUPPLY OPERATION
- LOW POWER CONSUMPTION
- SHORT CIRCUIT PROTECTION
- LOW DISTORTION, LOW NOISE
- HIGH GAIN-BANDWIDTH PRODUCT
- HIGH CHANNEL SEPARATION

## DESCRIPTION

The LS204 is a high performance dual operational amplifier with frequency and phase compensation built into the chip. The internal phase compensation allows stable operation as voltage follower in spite of its high gain-bandwidth products.
The circuit presents very stable electrical characteristics over the entire supply voltage range, and it particularly intended for professional and telecom applications (active filters, etc).

## APPLICATION INFORMATION

## Active low-pass filter :

## BUTTERWORTH

The Butterworth is a "maximally flat" amplitude response filter. Butterworth filters are used for filtering signals in data acquisition systems to prevent aliasing errors in sampled-data applications and for general purpose low-pass filtering.
The cutoff frequency, $\mathrm{f}_{\mathrm{c}}$, is the frequency at which the amplitude response is down 3 dB . The attenuation rate beyond the cutoff frequency is $n 6 \mathrm{~dB}$ per octave of frequency where n is the order (number of poles) of the filter.
Other characteristics :

- Flattest possible amplitude response.
- Excellent gain accuracy at low frequency end of passband.

Figure 10 : Amplitude Response.

BESSEL
The Bessel is a type of "linear phase" filter. Because of their linear phase characteristics, these filters approximate a constant time delay over a limited frequency range. Bessel filters pass transient waveforms with a minimum of distortion. They are also used to provide time delays for low pass filtering of modulated waveforms and as a "running average" type filter.
The maximum phase shift is $\frac{-n \pi}{2}$ radians where $n$ is the order (number of poles) of the filter. The cutoff frequency, fc , is defined as the frequency at which the phase shift is one half of this value. For accurate delay, the cutoff frequency should be twice the maxi-
mum signal frequency. The following table can beused to obtain the -3 dB frequency of the filter.

|  | 2 pole | 4 Pole | 6 Pole | P Pole |
| :---: | :---: | :---: | :---: | :---: |
| -3 dB Frequency | $0.77 \mathrm{f}_{\mathrm{c}}$ | $0.67 \mathrm{f}_{\mathrm{c}}$ | $0.57 \mathrm{f}_{\mathrm{c}}$ | $0.50 \mathrm{f}_{\mathrm{c}}$ |

Other characteristics :

- Selectivity not as great as Chebyschev or Butterworth.
- Very little overshoot response to step inputs.
- Fast rise time.

Figure 11 : Amplitude Response.

## CHEBYSCHEV

Chebyschev filters have greater selectivity than either Bessel or Butterworth at the expense of ripple in the passband.

Figure 12 : Amplitude Response ( $\pm 1 \mathrm{~dB}$ ripple).

## APPLICATION INFORMATION (continued)

Chebyschev filters are normally designed with peak-to-peak ripple values from 0.2 dB to 2 dB .
Increased ripple in the passband allows increased attenuation above the cutoff frequency.
The cutoff frequency is defined as the frequency at which the amplitude response passes through the
specified maximum ripple band and enters the stop band.
Other characteristics :

- Greater selectivity
- Very nonlinear phase response
- High overshoot response to step inputs

The table below shows the typical overshoot and settling time response of the low pass filters to a step input.

|  | Number of Poles | Peak <br> Overshoot <br> $\%$ Overshoot | Settling Time (\% of final value) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

Fixed $R=R 1=R 2$, we have (see fig. 13)

$$
\begin{aligned}
& C_{1}=\frac{1}{R} \quad \frac{\xi}{\omega_{c}} \\
& C_{2}=\frac{1}{R} \quad \frac{1}{\xi \omega_{c}}
\end{aligned}
$$

The diagram of fig. 14 shows the amplitude response for different values of damping factor $\xi$ in

## EXAMPLE

Figure 15 : 5th Order Low Pass Filter (Butterworth) with Unity Gain Configuration.

## APPLICATION INFORMATION (continued)

In the circuit of fig. 15 , for $f_{c}=3.4 \mathrm{KHz}$ and
$R_{i}=R_{1}=R_{2}=R_{3}=R_{4}=10 \mathrm{~K} \Omega$, we obtain :

$$
\begin{aligned}
& C_{i}=1.354 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=6.33 \mathrm{nF} \\
& C_{1}=0.421 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=1.97 \mathrm{nF} \\
& C_{2}=1.753 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=8.20 \mathrm{nF} \\
& C_{3}=0.309 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=1.45 \mathrm{nF} \\
& C_{4}=3.325 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=15.14 \mathrm{nF}
\end{aligned}
$$

The attenuation of the filter is 30 dB at 6.8 KHz and better than 60 dB at 15 KHz .

The same method, referring to Tab. Il and fig. 16, is used to design high-pass filter. In this case the damping factor is found by taking the reciprocal of the numbers in Tab. II. For $\mathrm{f}_{\mathrm{C}}=5 \mathrm{KHz}$ and $\mathrm{C}_{\mathrm{i}}=\mathrm{C}_{1}=\mathrm{C}_{2}$ $=\mathrm{C}_{3}=\mathrm{C}_{4}=1 \mathrm{nF}$ we obtain :

$$
\begin{aligned}
& \mathrm{R}_{\mathrm{i}}=\frac{1}{1.354} \cdot \frac{1}{\mathrm{C}} \cdot \frac{1}{2 \pi f_{\mathrm{c}}}=23.5 \mathrm{~K} \Omega \\
& \mathrm{R}_{1}=\frac{1}{0.421} \cdot \frac{1}{\mathrm{C}} \cdot \frac{1}{2 \pi \mathrm{f}_{\mathrm{c}}}=75.6 \mathrm{~K} \Omega \\
& \mathrm{R}_{2}=\frac{1}{1.753} \cdot \frac{1}{\mathrm{C}} \cdot \frac{1}{2 \pi f_{\mathrm{c}}}=18.2 \mathrm{~K} \Omega \\
& \mathrm{R}_{3}=\frac{1}{0.309} \cdot \frac{1}{\mathrm{C}} \cdot \frac{1}{2 \pi f_{\mathrm{c}}}=103 \mathrm{~K} \Omega \\
& \mathrm{R}_{4}=\frac{1}{3.325} \cdot \frac{1}{\mathrm{C}} \cdot \frac{1}{2 \pi f_{\mathrm{c}}}=9.6 \mathrm{~K} \Omega
\end{aligned}
$$

## HIGH PERFORMANCE QUAD OPERATIONAL AMPLIFIERS

- SINGLE OR SPLIT SUPPLY OPERATION
- VERY LOW POWER CONSUMPTION
- SHORT CIRCUIT PROTECTION
- LOW DISTORTION, LOW NOISE
- HIGH GAIN-BANDWIDTH PRODUCT
- HIGH CHANNEL SEPARATION

## DESCRIPTION

The LS404 is a high performance quad operational amplifier with frequency and phase compensation built into the chip. The internal phase compensation allows stable operation as voltage follower in spite of its high gain-bandwidth product. The circuit presents very stable electrical characteristics over the entire supply voltage range, and it is particularly intended for professional and telecom applications (active filters, etc.).
The patented input stage circuit allows small input signal swings below the negative supply voltage and prevents phase inversion when the input is over driven.

## APPLICATION INFORMATION

## Active low-pass filter :

## BUTTERWORTH

The Butterworth is a "maximally flat" amplitude response filter. Butterworth filters are used for filtering signals in data acquisition systems to prevent aliasing errors in sampled-data applications and for general purpose low-pass filtering.
The cutoff frequency, $\mathrm{f}_{\mathrm{c}}$, is the frequency at which the amplitude response in down 3 dB . The attenuation rate beyond the cutoff frequency is -n 6 dB per octave of frequency where n is the order (number of poles) of the filter.
Other characteristics :

- Flattest possible amplitude response.
- Excellent gain accuracy at low frequency end of passband.

Figure 10 : Amplitude Response.

BESSEL
The Bessel is a type of "linear phase" filter. Because of their linear phase characteristics, these filters approximate a constant time delay over a limited frequency range. Bessel filters pass transient waveforms with a minimum of distortion. They are also used to provide time delays for low pass filtering of modulated waveforms and as a "running average" type filter.

The maximum phase shift is $\frac{-n \pi}{2}$ radians where n is the order (number of poles) of the filter. The cutoff frequency, $\mathrm{f}_{\mathrm{c}}$, is defined as the frequency at which the phase shift is one half to this value. For accurate delay, the cutoff frequency should be twice the maxi-
mum signal frequency. The following table can be used to obtain the -3 dB frequency of the filter.

|  | 2 pole | 4 Pole | 6 Pole | 8 Pole |
| :---: | :---: | :---: | :---: | :---: |
| -3 dB Frequency | $0.77 \mathrm{f}_{\mathrm{c}}$ | $0.67 \mathrm{f}_{\mathrm{c}}$ | $0.57 \mathrm{f}_{\mathrm{c}}$ | $0.50 \mathrm{f}_{\mathrm{c}}$ |

Other characteristics :

- Selectivity not as great as Chebyschev or Butterworth.
- Very small overshoot response to step inputs.
- Fast rise time.

Figure 11 : Amplitude Response.

## CHEBYSCHEV

Chebyschev filters have greater selectivity than either Bessel or Butterworth at the expense of ripple in the passband.

Figure 12 : Amplitude Response ( $\pm 1 \mathrm{~dB}$ ripple).

## APPLICATION INFORMATION (continued)

Chebyschev filters are normally designed with peak-to-peak ripple values from 0.2 dB to 2 dB .
Increased ripple in the passband allows increased attenuation above the cutoff frequency.
The cutoff frequency is defined as the frequency at which the amplitude response passes through the
specified maximum ripple band and enters the stop band.

Other characteristics :

- Greater selectivity.
- Very nonlinear phase response.
- High overshoot response to step inputs.

The table below shows the typical overshoot and setting time response of the low pass filter to a step input.

|  | Number of Poles | Peak <br> Overshoot <br> \% Overshoot | Settling Time (\% of final value) |  |  |

Design of $2^{\text {nd }}$ order active low pass filter (Sallen and Key configuration unity gain op-amp).
Figure 13 : Filter Configuration.

## APPLICATION INFORMATION (continued)

Three parameters are needed to characterize the frequency and phase response of a $2^{\text {nd }}$ order active filter : the gain ( $\mathrm{G}_{\mathrm{v}}$ ), the damping factor $(\xi)$ or the Q factor $\left(\mathrm{Q}=(2 \xi)^{-1}\right)$, and the cutoff frequency ( $\mathrm{f}_{\mathrm{c}}$ ).
The higher order responses are obtained with a se-
ries of $2^{\text {nd }}$ order sections. A simple RC section is introduced when an odd filter is required.

The choice of ' $\xi$ ' (or Q-factor) determines the filter response (see table).

Table 1.

| Filter Response | $\boldsymbol{\xi}$ | $\mathbf{Q}$ | Cutoff Frequency $\mathrm{f}_{\mathbf{c}}$ |
| :--- | :---: | :---: | :--- |
| Bessel | $\frac{\sqrt{3}}{2}$ | $\frac{1}{\sqrt{3}}$ | Frequency at which Phase Shift is $-90^{\circ} \mathrm{C}$ |
| Butterworth | $\frac{\sqrt{2}}{2}$ | $\frac{1}{\sqrt{2}}$ | Frequency at which $\mathrm{G}_{\mathrm{v}}=-3 \mathrm{~dB}$ |
| Chebyschev | $<\frac{\sqrt{2}}{2}$ | $>\frac{1}{\sqrt{2}}$ | Frequency at which the amplitude response passes <br> through specified max. ripple band and enters the stop <br> band. |

Figure 14 : Filter Response vs. Damping Factor.

Fixed $R=R_{1}=R_{2}$, we have (see fig. 13)

$$
\begin{array}{ll}
C_{1}= & \frac{1}{R} \\
C_{2}=\frac{\xi}{\omega_{c}} & \frac{1}{\xi \omega_{c}}
\end{array}
$$

The diagram of fig. 14 shows the amplitude response for different values of damping factor $\xi$ in $2^{\text {nd }}$ order filters.

## EXAMPLE

Figure 15 : $5^{\text {th }}$ Order Low Pass Filter (Butterworth) with Unity Gain Configuration.

## APPLICATION INFORMATION (continued)

In the circuit of fig. 15, for $f_{c}=3.4 \mathrm{KHz}$ and
$R_{i}=R_{1}=R_{2}=R_{3}=R_{4}=10 \mathrm{~K} \Omega$, we obtain :

$$
\begin{aligned}
& C_{i}=1.354 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=6.33 \mathrm{nF} \\
& C_{1}=0.421 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=1.97 \mathrm{nF} \\
& C_{2}=1.753 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=8.20 \mathrm{nF} \\
& C_{3}=0.309 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=1.45 \mathrm{nF} \\
& C_{4}=3.325 \cdot \frac{1}{R} \cdot \frac{1}{2 \pi f_{c}}=15.14 \mathrm{nF}
\end{aligned}
$$

The attenuation of the filter is 30 dB at 6.8 KHz and better than 60 dB at 15 KHz .

The same method, referring to Tab. Il and fig. 16, is used to design high-pass filter. In this case the damping factor is found by taking the reciprocal of the numbers in Tab. II: For $\mathrm{f}_{\mathrm{C}}=5 \mathrm{KHz}$ and $\mathrm{C}_{\mathrm{i}}=\mathrm{C}_{1}=\mathrm{C}_{2}$ $=\mathrm{C}_{3}=\mathrm{C}_{4}=1 \mathrm{nF}$ we obtain :

$$
\begin{aligned}

\end{aligned}
$$

Figure 18 : Frequency Response of Band-pass Filter.

Figure 19 : Bandwidth of Band-pass Filter.

Figure 20 : Six-pole 355 Hz Low-pass Filter (chebychev type).

This is a 6-pole Chebychev type with $\pm 0.25 \mathrm{~dB}$ ripple in the passband. A decoupling stage is used to avoid the influence of the input impedance on the filter's characteristics. The attenuation is about

55 dB at 710 Hz and reaches 80 dB at 1065 Hz . The in band attenuation is limited in practice to the $\pm 0.25 \mathrm{~dB}$ ripple and does not exceed 0.5 dB at 0.9 fc .

Figure 21 : Subsonic Filter ( $\mathrm{G}_{\mathrm{v}}=0 \mathrm{~dB}$ ).

Figure 22 : High Cut Filter ( $\mathrm{G}_{\mathrm{v}}=0 \mathrm{~dB}$ ).

$$

- THE TEB1033 AND TEF1033 ARE PIN TO PIN REPLACEMENT OF THE LS204C AND LS204 RESPECTIVELY

## DESCRIPTION

The TEB1033, TEF1033 and TEC1033 are high performance dual-operational amplifiers intended for active filter applications. The internal phase compensation allows stable operation as voltage follower in spite of their high gain-bandwidth products.
The circuits present very stable electrical characteristics over the entire supply voltage range.

SGS-THOMSON
NaCROELECTRONDCS

## CMOS SINGLE OPERATIONAL AMPLIFIERS

- OFFSET NULL CAPABILITY (by external compensation)
- SYMMETRICAL OUTPUT CURRENTS
- HIGH GAIN BANDWIDTH PRODUCT
- THE TRANSFER FUNCTION IS LINEAR
- CONSUMPTION CURRENT AND DYNAMIC PARAMETERS ARE STABLE REGARDING THE VOLTAGE POWER SUPPLY VARIATIONS
- DYNAMIC CHARACTERISTICS ADJUSTABLE BY $I_{\text {set }}$
- VERY LARGE Iset RANGE
- PINCOMPATIBLETO SINGLE OPERATIONAL AMPLIFIER (UA776)
- STABLE AND LOW OFFSET VOLTAGE
- INTERNAL ELECTROSTATIC DISCHARGE (ESD) PROTECTION CIRCUITS
- THREE INPUT OFFSET VOLTAGE SELECTIONS : STANDARD ( 10 mV ), A ( 5 mV ), B ( 2 mV )

## DESCRIPTION

The TS271 is a low cost, low power single operational amplifier designed to operate with single or dual supplies. This operational amplifier uses the SGSTHOMSON Microelectronics silicon gate LIN MOS process giving it an excellent consumption-speed ratio. This amplifier is ideally suited for low consumption applications.
The power supply is externally programmable with a resistor connected between pins 8 and 4 . It allows to choose the best consumption-speed ratio and the consumption can be minimized according to the needed speed. These devices are specified for the following Iset current values : $1.5 \mu \mathrm{~A}, 25 \mu \mathrm{~A}, 130 \mu \mathrm{~A}$. The input impedance is similar to the J-FET input impedance : very high inpüt impedance and extremely low input offset and bias currents. They allow to minimize the static errors in low impedance applications.

## PACKAGE MECHANICAL DATA

8 PINS - PLASTIC DIP OR CERDIP

## PACKAGE MECHANICAL DATA (continued)

8 PINS - PLASTIC MICROPACKAGE SO

## CMOS DUAL OPERATIONAL AMPLIFIERS

- EXCELLENT PHASE MARGIN ON CAPACITANCE LOADS
- SYMMETRICAL OUTPUT CURRENTS
- HIGH GAIN BANDWIDTH PRODUCT FOR TS272
- LOW OUTPUT DYNAMIC IMPEDANCE
- THE TRANSFER FUNCTION IS LINEAR
- PIN COMPATIBLE TO STANDARD DUAL OPERATIONAL AMPLIFIERS (TL082 - LM358)
- STABLE AND LOW OFFSET VOLTAGE
- INTERNAL ELECTROSTATIC DISCHARGE (ESD) PROTECTION CIRCUITS
- THREE INPUT OFFSET VOLTAGE SELECTIONS : STANDARD ( 10 mV ), A ( 5 mV ), B ( 2 mV )

## DESCRIPTION

The TS272 series are low cost, low power dual operational amplifiers designed to operate with single or dual supplies. These operational amplifiers use the SGS THOMSON Microelectronics silicon gate LIN MOS process giving them an excellent consumption speed ratio. These series are ideally suited for low consumption applications.
Three power consumptions are available allowing to have always the best consumption-speed ratio.

- Icc $=\mathbf{1 0} \mu \mathrm{A}$ per amplifier : TS27L2 (Low bias versions)
- Icc = $\mathbf{1 5 0} \mu \mathrm{A}$ per amplifier : TS27M2 (Medium bias versions)
- Icc = 1 mA per amplifier : TS272 (High bias versions)

The input impedance is similar to the J-FET input impedance. Very high input impedance and extremely low input offset and bias currents. They allow to minimize the static errors in low impedance applications.

## PACKAGE MECHANICAL DATA

8 PINS - PLASTIC DIP OR CERDIP

SCS-THOMSON

PACKAGE MECHANICAL DATA (continued)
8 PINS - PLASTIC MICROPACKAGE SO

## CMOS QUAD OPERATIONAL AMPLIFIERS

- EXCELLENT PHASE MARGIN ON CAPACITIVE LOADS
- SYMMETRICAL OUTPUT CURRENTS
. HIGH GAIN BANDWIDTH PRODUCT FOR TS274
- LOW OUTPUT DYNAMIC IMPEDANCE
- THE TRANSFER FUNCTION IS LINEAR
- PIN COMPATIBLE TO STANDARD QUAD OPERATIONAL AMPLIFIERS (TL084-LM324)
- STABLE AND LOW OFFSET VOLTAGE
- INTERNAL ELECTROSTATIC DISCHARGE (ESD) PROTECTION CIRCUITS
- THREE INPUT OFFSET VOLTAGE SELECTIONS : STANDARD ( 10 mV ), A ( 5 mV ), B ( 2 mV )

## PIN CONNECTIONS (top view)

- Inverting input 1
- Non-inverting input 1
- $\mathrm{VCC}^{+}$
- Non-inverting input 2
- Inverting input 2
- Output 2
- Output 3
- Inverting input 3
- Non-inverting input 3
- $\mathrm{V}_{\mathrm{CC}}{ }^{-}$
- Non-inverting input 4
- Inverting input 4
- Output 4

PACKAGE MECHANICAL DATA
14 PINS - PLASTIC DIP OR CERDIP

14 pus

PACKAGE MECHANICAL DATA (continued)
14 PINS - PLASTIC MICROPACKAGE SO

## CMOS DUAL DIFFERENTIAL COMPARATOR

ADVANCE DATA

- WIDE SINGLE SUPPLY RANGE OR DUAL SUPPLIES 4 V TO 10 V OR $\pm 2 \mathrm{~V}$ TO $\pm 5 \mathrm{~V}$
- VERY LOW SUPPLY CURRENT:0.4 mA INDEPENDENT OF SUPPLY VOLTAGE
- EXTREMELY LOW INPUT BIAS CURRENT : 1 pA TYP
- EXTREMELY LOW INPUT OFFSET CURRENT : 1 pA TYP
- LOW INPUT OFFSET VOLTAGE
- INPUT COMMON-MODE VOLTAGE RANGE INCLUDES GND
- LOW OUTPUT SATURATION VOLTAGE 150 mV TYP
- OUTPUT COMPATIBLE WITH TTL.MOS AND CMOS
- BUILT-IN ESD PROTECTION
- HIGH INPUT IMPEDANCE $10^{12} \Omega$ TYP
- FAST REPONSE TIME : 200 NS TYP FOR TTL LEVEL INPUT STEP

## DESCRIPTION

These devices consist of two independent precision voltage comparators, designed to operate with single or dual supplies.
These differential comparators use the SGS THOMSON Microelectronics silicon lin MOS process giving them an excellent consumption-speed ratio.
These devices are ideally suited for low consumption applications.

## PIN CONNECTIONS (top view)

E88TS272-01

1 - Output 1
2 - Inverting input 1
3 - Non-inverting Input 1
4 - Vcc ${ }^{-}$
5 - Non-inverting input 2
6 - Inverting input 2
7 - Output 2
$8-V_{c c}{ }^{+}$

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter |  | Value | Unit |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\text {CC }}$ | Supply Voltage (note 1) |  | 12 | V |
| $V_{\text {id }}$ | Differential Input Voltage (note 2) |  | $\pm 12$ | V |
| $V_{i} \quad$. | Input Voltage (note 3) |  | 12 | V |
| $\mathrm{V}_{0}$ | Output Voltage |  | 12 | V |
| 10 | Output Current |  | 20 | mA |
|  | Duration of Output Short-circuit to GND (note 4) |  | Unlimited |  |
| Toper | Operating Free-air Temperature | $\begin{aligned} & \hline \text { TS372C } \\ & \text { TS3721 } \\ & \text { TS372M } \end{aligned}$ | $\begin{gathered} 0 \text { to } 70 \\ -40 \text { to } 105 \\ -55 \text { to } 125 \end{gathered}$ | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\text {stg }}$ | Storage Temperature |  | -65 to 150 | ${ }^{\circ} \mathrm{C}$ |

Notes: 1. All voltage values, except differential voltages are with respect to network ground terminal.
2. Differential voltages are at the non-inverting input terminal with respect to the input terminal.
3. The magnitude of the input voltage must never exceed the magnitude of the positive supply voltage.
4. Short circuit from outputs to $\mathrm{V}_{\mathrm{cc}}{ }^{+}$can cause excessive heating and eventual destruction.

## OPERATING CONDITIONS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $V_{c c}$ | Supply Voltage Range | 4 to 10 | V |
| $\mathrm{~V}_{\mathrm{CC}}$ | Min Supply Voltage (for selected devices) | 3 | V |
| $\mathrm{~V}_{\mathrm{CC}}$ | Max Supply Voltage | 12 | V |

ELECTRICAL CHARACTERISTICS $\left(\mathrm{V}_{\mathrm{CC}}=+5 \mathrm{~V}, \mathrm{~T}=25^{\circ} \mathrm{C}\right)$

| Symbol | Parameter | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Min. | Typ. | Max. |  |
| $\mathrm{V}_{\text {io }}$ | Input Offset Voltage for $\mathrm{V}_{\text {IC }}=\mathrm{V}_{\text {ICR }}$ Min ( (note 1) |  | 2 | 10 | mV |
| $\mathrm{I}_{\text {io }}$ | Input Offset Current (note 1) |  | 1 |  | pA |
| $\mathrm{I}_{\text {ib }}$ | Input Bias Current |  | 1 |  | pA |
| VICR | Input Common Mode Voltage Range | $\left\|\begin{array}{\|c\|} 0 \text { to } V_{c c} \\ -1.5 \mathrm{~V} \end{array}\right\|$ |  |  | V |
| $\mathrm{A}_{\mathrm{vd}}$ | Large Signal Voltage Gain $\mathrm{V}_{\mathrm{CC}}=10 \mathrm{~V} ; \mathrm{R}_{\mathrm{L}}>15 \mathrm{~K} \Omega$ at $\mathrm{V}_{\mathrm{CC}}$ |  | 200 |  | V/mV |
| $\mathrm{I}_{\text {oh }}$ | High Level Output Current $\mathrm{V}_{\text {id }}=1 \mathrm{~V} ; \mathrm{V}_{\text {oh }}=+5 \mathrm{~V}$ |  | 0.1 |  | nA |
| $\mathrm{V}_{0}$ | Low. Level Output Voltage $\mathrm{V}_{\text {id }}=1 \mathrm{~V}$; $\mathrm{I}_{01}=4 \mathrm{~mA}$ |  | ${ }^{-} 150$ | 400 | mV |
| Icc | Supply Current (4 comparators) $\mathrm{V}_{1 \mathrm{~d}}=-1 \mathrm{~V} ; \mathrm{R}_{\mathrm{L}}=\infty$ |  | 0.4 | 1 | mA |
| $l_{01}$ | Low Level Output Current $\mathrm{V}_{\text {id }}=-1 \mathrm{~V} ; \mathrm{V}_{\mathrm{OL}}=1.5 \mathrm{~V}$ | 6 | 16 |  | mA |
| Tre | Response Time $R_{L}=5.1 \mathrm{~K} \Omega ; \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ Overdrive 5 mV (note 2) |  | 600 |  | ns |
| $\mathrm{T}_{\mathrm{re}}$ | Response Time $\mathrm{R}_{\mathrm{L}}=5.1 \mathrm{~K} \Omega ; \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ TTL Input (note 2) |  | 200 |  | ns |

Notes: 1. The offset voltage and offset current which are given are the maximum values required to drive the output down to 400 mV or up to 4 V with $\mathrm{R}_{\mathrm{L}}=2.5 \mathrm{~K} \Omega$ to $\mathrm{V}_{\mathrm{cc}}$.
2. The response time which is specified is the interval between the input signal and the instant when the output signal crosses 1.4 V .

- BUILT-IN ESD PROTECTION
- HIGH INPUT IMPEDANCE $10^{12} \Omega$ TYP
- FAST REPONSE TIME : 200 NS TYP FOR TTL LEVEL INPUT STEP

## DESCRIPTION

These devices consist of four independent precision voltage comparators, designed to operate with single or dual supplies.
These differential comparators use the SGS THOMSON Microelectronics silicon lin MOS process giving them an excellent consumption-speed ratio.
These devices are ideally suited for low consumption applications.

## ABSOLUTE MAXIMUM RATINGS

| Symbol | Parameter |  | Value | Unit |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{V}_{\mathrm{cc}}$ | Supply Voltage (note 1) |  | 12 | V |
| $V_{\text {id }}$ | Differential Input Voltage (note 2) |  | $\pm 12$ | V |
| $V_{i}$ | Input Voltage (note 3) |  | 12 | V |
| $\mathrm{V}_{0}$ | Output Voltage |  | 12 | V |
| 10 | Output Current |  | 20 | mA |
|  | Duration of Output Short-circuit to GND (note 4) |  | Unlimited |  |
| Toper | Operating Free-air Temperature | $\begin{aligned} & \hline \text { TS374C } \\ & \text { TS3741 } \\ & \text { TS374M } \end{aligned}$ | $\begin{gathered} 0 \text { to } 70 \\ -40 \text { to } 105 \\ -55 \text { to } 125 \end{gathered}$ | ${ }^{\circ} \mathrm{C}$ * |
| $\mathrm{T}_{\text {stg }}$ | Storage Temperature |  | -65 to 150 | ${ }^{\circ} \mathrm{C}$ |

Notes : 1. All voltage values, except differential voltages are with respect to network ground terminal.
2. Differential voltages are at the non-inverting input terminal with respect to the input terminal.
3. The magnitude of the input voltage must never exceed the magnitude of the positive supply voltage.
4. Short circuit from outputs to $\mathrm{Vcc}^{+}$can cause excessive heating and eventual destruction.

OPERATING CONDITIONS

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $\mathrm{V}_{\mathrm{CC}}$ | Supply Voltage Range | 4 to 10 | V |
| $\mathrm{~V}_{\mathrm{CC}}$ | Min Supply Voltage (for selected devices) | 3 | V |
| $\mathrm{~V}_{\mathrm{CC}}$ | Max Supply Voltage | 12 | V |

ELECTRICAL CHARACTERISTICS $\left(V_{C C}=+5 \mathrm{~V}, \mathrm{~T}=25^{\circ} \mathrm{C}\right)$

| Symbol | Parameter | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Min. | Typ. | Max. |  |
| $V_{i o}$ | Input Offset Voltage for $\mathrm{V}_{\text {IC }}=\mathrm{V}_{\text {ICR Min }}$ ( ( ${ }^{\text {cte 1) }}$ |  | 2 | 10 | mV |
| $\mathrm{l}_{10}$ | Input Offset Current (note 1) |  | 1 |  | pA |
| $\mathrm{l}_{\text {ib }}$ | Input Bias Current |  | 1 |  | pA |
| $V_{\text {ICR }}$ | Input Common Mode Voltage Range | $\left\|\begin{array}{c} 0 \text { to } V_{\mathrm{cc}} \\ -1.5 \mathrm{~V} \end{array}\right\|$ |  |  | V |
| Avd | Large Signal Voltage Gain $\mathrm{V}_{C C}=10 \mathrm{~V}$; $\mathrm{R}_{\mathrm{L}}>15 \mathrm{~K} \Omega$ at $\mathrm{V}_{\mathrm{CC}}$ |  | 200 |  | V/mV |
| Ioh | High Level Output Current $\mathrm{V}_{\text {id }}=1 \mathrm{~V}$; $\mathrm{V}_{\text {oh }}=+5 \mathrm{~V}$ |  | 0.1 |  | nA |
| $V_{01}$ | Low Level Output Voltage $\mathrm{V}_{\text {id }}=1 \mathrm{~V}$; $\mathrm{I}_{\text {ol }}=4 \mathrm{~mA}$ |  | 150 | 400 | mV |
| lcc | Supply Current (4 comparators) $\mathrm{V}_{\text {id }}=-1 \mathrm{~V} ; \mathrm{R}_{\mathrm{L}}=\infty$ |  | 0.4 | 1 | mA |
| 101 | Low Level Output Current $\mathrm{V}_{\text {id }}=-1 \mathrm{~V}$; $\mathrm{V}_{\mathrm{OL}}=1.5 \mathrm{~V}$ | 6 | 16 |  | mA |
| $\mathrm{T}_{\text {re }}$ | Response Time $\mathrm{R}_{\mathrm{L}}=5.1 \mathrm{~K} \Omega ; \mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ Overdrive 5 mV (note 2) |  | 600 |  | ns |
| $\mathrm{T}_{\text {re }}$ | Response Time $\mathrm{R}_{\mathrm{L}}=5.1 \mathrm{~K} \Omega$; $\mathrm{C}_{\mathrm{L}}=15 \mathrm{pF}$ TTL Input (note 2) |  | 200 |  | ns |

Notes : 1. The offset voltage and offset current which are given are the maximum values required to drive the output down to 400 mV or up to 4 V with $\mathrm{R}_{\mathrm{L}}=2.5 \mathrm{~K} \Omega$ to V Cc .
2. The response time which is specified is the interval between the input signal and the instant when the output signal crosses 1.4 V .

ORDERING INFORMATION

| Part Number | Temperature Range | Package |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | N | D | J |
| TS374 | 0 to 70 | $\bullet$ | $\bullet$ |  |
| TS374I | - 40 to 105 | - | - |  |
| TS374M | - 55 to 125 |  |  | - |
| Examples: TS374ID |  |  |  |  |

## PACKAGE MECHANICAL DATA

14 PINS - PLASTIC DIP OR CERDIP

14 PINS - PLASTIC MICROPACKAGE SO

## PROTECTION CIRCUITS

## UNI-AND BIDIRECTIONAL TRANSIENT VOLTAGE SUPPRESSORS

- HIGH SURGE CAPABILITY : 400 W / 1 ms EXPO
- VERY FAST CLAMPING TIME : 1 ps FOR UNIDIRECTIONAL TYPES 5 ns FOR BIDIRECTIONAL TYPES
- LARGE VOLTAGE RANGE :
$5.8 \mathrm{~V} \rightarrow 376 \mathrm{~V}$
- ORDER CODE:

TYPE NUMBER FOR UNIDIRECTIONAL TYPES, TYPE NUMBER + SUFFIX B FOR BIDIRECTIONAL TYPES

## DESCRIPTION

Transient voltage suppressor diodes especially useful in protecting integrated circuits, MOS, hybrids and other voltage-sensitive semiconductors and components.

ABSOLUTE MAXIMUM RATINGS (limiting values)

| Symbol | Parameter |  | Value | Unit |
| :---: | :---: | :---: | :---: | :---: |
| $P_{p}$ | Peak Pulse Power for 1 ms Exponential Pulse | $\begin{gathered} \mathrm{T}_{\mathrm{j}} \text { Initial }=25^{\circ} \mathrm{C} \\ \text { See note } 1 \end{gathered}$ | 400 | W |
| P | Power Dissipation on Infinite Heatsink | $\mathrm{T}_{\text {amb }}=50^{\circ} \mathrm{C}$ | 1.7 | W |
| $\mathrm{I}_{\text {FSM }}$ | Non Repetitive Surge Peak Forward Current for Unidirectional Types | $\begin{gathered} \mathrm{T}_{\mathrm{j}} \text { Initial }=25^{\circ} \mathrm{C} \\ \mathrm{t}=10 \mathrm{~ms} \end{gathered}$ | 50 | A |
| $\begin{gathered} \mathrm{T}_{\text {stg }} \\ \mathrm{T}_{\mathrm{j}} \end{gathered}$ | Storage and Operating Junction Temperature Range |  | $\begin{gathered} -55 \text { to } 150 \\ 150 \end{gathered}$ | $\begin{aligned} & { }^{\circ} \mathrm{C} \\ & { }^{\circ} \mathrm{C} \end{aligned}$ |
| $\mathrm{T}_{\mathrm{L}}$ | Maximum Lead Temperature for Soldering During 10 s at 4 mm from Case |  | 230 | ${ }^{\circ} \mathrm{C}$ |

## THERMAL RESISTANCE

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $R_{\text {th(j-1) }}$ | Junction-leads on Infinite Heatsink for $L_{\text {lead }}=10 \mathrm{~mm}$ | 60 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

Note : 1. For surges upper than the maximum values, the diode will present a short-circuit anode-cathode.

# UNI-AND BIDIRECTIONAL TRANSIENT VOLTAGE SUPPRESSORS 

- HIGH SURGE CAPABILITY :

600 W / 1 ms EXPO

- VERY FAST CLAMPING TIME : 1 ps FOR UNIDIRECTIONAL TYPES
5 ns FOR BIDIRECTIONAL TYPES
- LARGE VOLTAGE RANGE :
$5.8 \mathrm{~V} \rightarrow 376 \mathrm{~V}$
- ORDER CODE :

TYPE NUMBER FOR UNIDIRECTIONAL TYPES, TYPE NUMBER + SUFFIX C FOR BIDIRECTIONAL TYPES

## DESCRIPTION

Transient voltage suppressor diodes especially useful in protecting integrated circuits, MOS, hybrids and other voltage-sensitive semiconductors and components.

ABSOLUTE RATINGS (limiting values)

| Symbol | Parameter |  | Value | Unit |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{P}_{\mathrm{p}}$ | Peak Pulse Power for 1 ms Exponential Pulse | $\begin{aligned} & \mathrm{T}_{\mathrm{j}} \text { Initial }=25^{\circ} \mathrm{C} \\ & \text { See note } 1 \end{aligned}$ | 600 | W |
| P | Power Dissipation on Infinite Heatsink | $\mathrm{T}_{\text {amb }}=75^{\circ} \mathrm{C}$ | 5 | W |
| $\mathrm{I}_{\text {FSM }}$ | Non Repetitive Surge Peak Forward Current for Unidirectional Types | $\begin{gathered} \mathrm{T}_{\mathrm{i}} \ln \text { itial }=25^{\circ} \mathrm{C} \\ \mathrm{t}=10 \mathrm{~ms} \end{gathered}$ | 100 | A |
| $\begin{gathered} \mathrm{T}_{\text {stg }} \\ \mathrm{T}_{\mathrm{j}} \\ \hline \end{gathered}$ | Storage and Operating Junction Temperature Range |  | $\begin{gathered} -55 \text { to } 175 \\ 175 \\ \hline \end{gathered}$ | $\begin{aligned} & { }^{\circ} \mathrm{C} \\ & { }^{\circ} \mathrm{C} \\ & \hline \end{aligned}$ |
| TL | Maximum Lead Temperature for Soldering During 10 s at 4 mm from Case |  | 230 | ${ }^{\circ} \mathrm{C}$ |

## THERMAL RESISTANCE

| Symbol | Parameter | Value | Unit |
| :---: | :---: | :---: | :---: |
| $R_{\mathrm{th}(\mathrm{j}-1)}$ | Junction-leads on Infinite Heatsink for $L_{\text {lead }}=10 \mathrm{~mm}$ | 20 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

Note : 1. For surges upper than the maximum values, the diode will present a short-circuit anode-cathode.

ELECTRICAL CHARACTERISTICS $\left(T_{j}=25^{\circ} \mathrm{C}\right)$

| Symbol | Parameter |  | Value |
| :---: | :---: | :---: | :---: |
| V FM | Stand-off Voltage |  |  |
| $\mathrm{V}_{\text {(BR) }}$ | Breakdown Voltage |  |  |
| $V_{\text {(CL) }}$ | Clamping Voltage |  | See tables |
| $\mathrm{l}_{\mathrm{pp}}$ | Peak Pulse Current |  |  |
| $\alpha_{T}$ | Temperature Coefficient of $\mathrm{V}_{\text {(BR) }}$ |  |  |
| C | Capacitance |  |  |
| $\mathrm{t}_{\text {clamping }}$ | Clamping Time (0 volt to $\mathrm{V}_{(\mathrm{BR})}$ ) | Unidirectional Types | 1 ps max. |
|  |  | Bidirectional Types | 5 ns max. |
| $\mathrm{V}_{\mathrm{FM}}$ | Forward Voltage Drop for Unidirectional Types ( $\mathrm{I}_{\text {FM }}=50 \mathrm{~A}$ ) |  | 3.5 V max. |

* Pulse test $t_{p} \leq 50 \mathrm{~ms} \delta<2 \%$.
** Divide these values by 2 for bidirectional types.
For bidirectional types P6KE6V8CP $\rightarrow$ 11CA, IRM must be double that specified for unidirectional types.
For bidirectional types, electrical characteristics apply in both directions.
$P$ : Preferred device.

## DESCRIPTION

Transient voltage suppressor diodes especially useful in protecting integrated circuits, MOS, hybrids and other voltage-sensitive semiconductors and components.

SURFACE MOUNT TRANSIL FEATURES

- A PERFECT PICK AND PLACE BEHAVIOUR - AN EXCELLENT ON BOARD STABILITY
- A FULL COMPATIBILITY WITH BOTH GLUING AND PASTE SOLDERING TECHNOLOGIES
- BODY MARKED WITH TYPE CODE AND LOGO
- STANDARD PACKAGING : 12 mm TAPE (EIA STD. RS481)
- TINNED COPPER LEADS
- HIGH TEMPERATURE RESISTANT RESIN

Laser marking.
The logo indicates cathode for unidirectional types.

## FOOT PRINT DIMENSIONS (Millimeters)

Fig. 1 - Peak pulse power versus exponential pulse duration.

Fig. 2 - Clamping voltage versus peak pulse current.
exponential waveform
$t=20 \mu \mathrm{~s}$..........
$\mathrm{t}=1 \mathrm{~ms}$-ー-
$\mathrm{t}=10 \mathrm{~ms}$

Note : The curves of the figure 2 are specified for a junction temperature of $25{ }^{\circ} \mathrm{C}$ before surge. The given results may be extrapolated for other junction temperatures by using the following formula: $\Delta V$ (BR) $=\alpha_{T}\left(V\right.$ (BR)) $X\left[T_{j}-25\right] \times V_{\text {(BA) }}$ For intermediate voltages, extrapolate the given results.

Fig. 3 - Allowable power dissipation versus junction temperature.

Fig. 5 - Thermal resistance junctionambient versus Cu surface (printed circuit).

Fig. 6 - Transient thermal impedance junction-ambient versus pulse duration.

DBBSMETP5

Fig. 4 - Power dissipation versus ambient temperature.

Fig. 7 - Peak forward current versus peak forward voltage drop (typical values for unidirectional types).

## UNI-AND BIDIRECTIONAL TRANSIENT VOLTAGE SUPPRESSORS

- HIGH SURGE CAPABILITY :
$1.5 \mathrm{~kW} / 1 \mathrm{~ms}$ EXPO
- VERY FAST CLAMPING TIME :

1 ps FOR UNIDIRECTIONAL TYPES
5 ns FOR BIDIRECTIONAL TYPES

- LARGE VOLTAGE RANGE :
$5.5 \mathrm{~V} \rightarrow 188 \mathrm{~V}$
- ORDER CODE :

TYPE NUMBER FOR UNIDIRECTIONAL TYPES, TYPE NUMBER + SUFFIX C FOR BIDIRECTIONAL TYPES

## DESCRIPTION

Transient voltage suppressor diodes especially useful in protecting integrated circuits, MOS, hybrids and other voltage-sensitive semiconductors and components.

## SURFACE MOUNT TRANSIL FEATURES

- A PERFECT PICK AND PLACE BEHAVIOUR
- AN EXCELLENT ON BOARD STABILITY
- A FULL COMPATIBILITY WITH BOTH GLUING AND PASTE SOLDERING TECHNOLOGIES
- BODY MARKED WITH TYPE CODE AND LOGO
- STANDARD PACKAGING: 12 mm TAPE (EIA STD. RS481)
- TINNED COPPER LEADS
- HIGH TEMPERATURE RESISTANT RESIN

ABSOLUTE RATINGS (limiting values)

| Symbol | Parameter |  | Value | Unit |

$\mathrm{t}=10 \mathrm{~ms}$

Note : The curves of the figure 2 are specified for a junction temperature of $25{ }^{\circ} \mathrm{C}$ before surge. The given results may be extrapolated for other junction temperatures by using the following formula: $\Delta V(B R)=\alpha_{T}(V(B R)) \times\left[T_{j}-25\right] \times V_{(B R)}$ For intermediate voltages, extrapolate the given results.

## DESCRIPTION

The L3100B/B1 is a transient overvoltage suppressor/overcurrent arrester designed to protect sensitive components in electronic telephones and telecommunication equipments against transients caused by lightning, induction from power lines, etc. The L3100B/B1 characteristic, that is its firing voltage and current, can be easily programmed by means of inexpensive external components ; more over, since this device recoveres automatically when the surge current falls below a fixed holding current, it may be used on remotely supplied lines. Finally, if destroyed, it becomes a permanent short circuit.

## THERMAL RESISTANCE

| Symbol | Parameter | Value | Unit |  |
| :--- | :---: | :---: | :---: | :---: |
| $\mathrm{R}_{\mathrm{th}(\mathrm{j}-\mathrm{a})}$ | Junction to Ambient |  | 80 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| ${ }^{*}$ ANSI STD C62. |  |  |  |  |
| Pulse wave form |  |  |  |  |
|  |  |  |  |  |

ELECTRICAL CHARACTERISTICS
( $\mathrm{T}_{\mathrm{j}}=25^{\circ} \mathrm{C}$ )

| Symbol | Parameter |
| :---: | :--- |
| $\mathrm{V}_{\mathrm{RM}}$ | Stand-off Voltage |
| $\mathrm{V}_{\mathrm{BR}}$ | Breakdown Voltage |
| $\mathrm{V}_{\mathrm{BO}}$ | Clamping Voltage |
| $\mathrm{I}_{\mathrm{H}}$ | Holding Current |
| $\mathrm{V}_{\mathrm{T}}$ | On-state Voltage @ $\mathrm{I}_{\mathrm{T}}$ |
| $\mathrm{I}_{\mathrm{BO}}$ | Breakover Current |
| $\mathrm{I}_{\mathrm{Pp}}$ | Peak-pulse Current |
| $\mathrm{V}_{\mathrm{GN}}$ | Gate Voltage |
| $\mathrm{I}_{\mathrm{GN}}$ | Firing Gate N Current |
| $\mathrm{V}_{\mathrm{RGN}}$ | Reverse Gate N Voltage |
| $\mathrm{I}_{\mathrm{GP}}$ | Firing Gate $P$ Current |

## OPERATION WITHOUT GATE

| Type | $\underset{\text { max. }}{\mathrm{I}_{\mathrm{RM}} @ V_{\mathrm{FM}}}$ |  | $\underset{\min .}{V_{\text {BR }}} \text { max. } @ I_{R}$ |  |  | $\mathrm{V}_{\text {во }}$ @ $\mathrm{I}_{\text {во }}$ max. min. max. See note 2 |  |  | $\begin{gathered} \mathrm{I}_{\mathrm{H}} \\ \mathrm{~min} . \end{gathered}$ | $\begin{gathered} V_{T} \\ \text { typ. } \\ \mathrm{I}_{\mathrm{T}} \stackrel{1}{=} \mathrm{A} \end{gathered}$ | $\begin{gathered} C \\ \max _{\mathrm{R}}=5 \mathrm{~V} \\ \mathrm{~F}=1 \mathrm{MHz} \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | ( $\mu \mathrm{A}$ ) | (V) | (V) | (V) | (mA) | (V) | (mA) | (mA) | (mA) | (V) | (pF) |
| L3100B/B1 | $\begin{gathered} 6 \\ 40 \end{gathered}$ | $\begin{gathered} 60 \\ 250 \end{gathered}$ | $\begin{array}{\|l} 255(3) \\ 265(4) \end{array}$ |  | 1 | 350 | 200 | 500 | $\begin{aligned} & 210(3) \\ & 280(4) \end{aligned}$ | 2 | 100 |

## OPERATION WITH GATES

| Type | $\begin{gathered} V_{G N} \\ (V)^{\prime} . \\ I_{G}=200 \mathrm{~mA} \end{gathered}$ |  | $\begin{gathered} \mathrm{I}_{\mathrm{GN}} \\ (\mathrm{~mA}) \\ \mathrm{V}_{\mathrm{A}}-\mathrm{C}=100 \mathrm{~V} \end{gathered}$ |  | $\begin{gathered} V_{\mathrm{RGN}} \\ (\mathrm{~V}) \\ \mathrm{I}_{\mathrm{G}}=-1 \mathrm{~mA} \end{gathered}$ |  | $\begin{gathered} \mathrm{I}_{\mathrm{GP}} \\ (\mathrm{~mA}) \\ \mathrm{V}_{\mathrm{A}}-\mathrm{C}=100 \mathrm{~V} \end{gathered}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | min. | max. | min. | max. | min. | max. | min. | max. |
| L3100B/B1 | 0.6 | 1.8 | 30 | 200 | 0.7 |  |  | 150 |

Notes: 1. Reverse characteristic : $\mathrm{I}_{\mathrm{R}}<1 \mathrm{~mA} @ \mathrm{~V}_{\mathrm{R}}=0.7 \mathrm{~V}$.
2. These devices are not designed to function as zeners; continuous operation between 1 mA and $\mathrm{l}_{\mathrm{Bo}}$ will damage them.
3. L3100B1

[^0]:    * Adjustable to both higher and lower values with external components.
    ** The dynamic output can be doubled. See application notes at R14.

[^1]:    * Adjustable to both higher and lower values with external components.
    ** The dynamic output can be doubled. See application notes at R14.

[^2]:    * Adjustable to both higher and lower values with external components.
    ** The dynamic output can be doubled. See application notes at R14.

[^3]:    * Input resistor of $1.5 \mathrm{~K} \Omega$ is active until $V_{T R}$ of input inverter is reached.

[^4]:    Note : 1. Low output voltage is less than 50 mV .

[^5]:    * Pulse test $t_{p} \leq 50 \mathrm{~ms} \delta<2 \%$.
    ** Divide these values by 2 for bidirectional types.
    For bidirectional types, electrical characteristics apply in both directions.
    $P$ : Preferred device.

[^6]:    Cooling method : by convection (method A).
    Marking : type number ; white band indicates cathode for unidirectional types.
    Weight: 0.9 g .

[^7]:    Cooling method : by convection (method A).
    Marking : type number ; white band indicates cathode for unidirectional types.
    Weight: 1 g .

[^8]:    * Pulse test $t_{p} \leq 50 \mathrm{~ms} \quad \delta<2 \%$.
    ** Divide these values by 2 for bidirectional types.
    For bidirectional types, electrical characteristics apply in both directions.

[^9]:    P: Preferred device.
    (1) : These volages are on request. Consult us.

[^10]:    P: Preferred device.
    (1) : These voltages are on request. Consult us.
