PREFACE

This manual describes the FORTRAN Extended language (version 4.0) for the CONTROL DATA® CYBER 70/Models 72, 73 and 74, and 6200, 6400, 6500, 6600 and 6700 computers, and FORTRAN Extended (version 2.0) for the CONTROL DATA CYBER 70/Model 76, 7600, 7601-1 and 761X computers. It is assumed that the reader has knowledge of an existing FORTRAN language and the CONTROL DATA CYBER 70, 6000 Series or 7600 computer systems. FORTRAN Extended is designed to comply with American National Standards Institute FORTRAN language.

The FORTRAN compiler operates in conjunction with version 3.0 COMPASS assembly language processor under control of the 6000 SCOPE operating system (version 3.4), and 7000 SCOPE operating system (version 2.0). The FORTRAN compiler makes optimum use of the high speed execution characteristics of the CONTROL DATA CYBER 70, 6000 Series and 7600 computer systems. It utilizes the SCOPE operating system’s multi-programming features to provide compilation and execution within a single job operation, as well as simultaneous compilation of several programs.

The following new features are included in FORTRAN Extended:

- LEVEL statement
- IMPLICIT statement
- Hollerith strings in output lists
- Expressions in output lists
- Quote delimited Hollerith strings
- Exclusive OR function
- Messages on STOP and PAUSE statements
- Line limit on output file at execution time
- Syntax scan only during compilation
- Program listings suppressed but reference map produced
- Rewrite in place, mass storage
- Multiple systems texts and local texts for intermixed COMPASS programs

This manual is in three parts. The reference section, Part 1, contains a full description of the FORTRAN Extended language.
Part 2 consists of a set of sample programs with input cards and output. Each program is preceded by a short introduction which explains some of the more difficult aspects of the language for the less experienced FORTRAN programmer.

Part 3 contains mainly systems information, although the applications programmer will be interested in the character set in section 1 and the compilation and execution diagnostics in section 2.

Throughout the manual, CONTROL DATA extensions to the FORTRAN language are indicated by blue type. Otherwise, FORTRAN Extended conforms to ANSI standards.

Information which applies only to the CONTROL DATA CYBER 70/Model 76 and 7600 computers is indicated by red type.

Information which applies only to the CONTROL DATA CYBER 70/Models 72, 73 and 74, and 6000 Series computers is indicated by green type.

INDEX Index-1
The following symbols are used in the descriptions of FORTRAN Extended statements:

- \( v \) variable or array element
- \( sn \) statement label
- \( iv \) integer variable
- \( name \) symbolic name
- \( u \) input/output unit:
  - 1- or 2-digit decimal integer constant
  - integer variable with value of: 1-99 or display code file name
- \( fn \) format designator
- \( iolist \) input/output list

Other forms are defined individually in the following list of statements.

**ASSIGNMENT STATEMENTS**

\[ v = \text{arithmetic expression} \]

\[ \text{logical } v = \text{logical or relational expression} \]

\[ v = \text{masking expression} \]

**MULTIPLE ASSIGNMENT**

\[ v_1 = v_2 = \ldots = v_n = \text{expression} \]

**CONTROL STATEMENTS**

A FORTRAN program contains executable and non-executable statements. Executable statements specify action the program is to take, and non-executable statements describe characteristics of operands, statement functions, arrangement of data, and format of data.

The FORTRAN source program is written on the coding form illustrated in figure 1. Each line on the coding form represents an 80-column card. The source language character set (section 1, part 3) is used to code statements.

**THE FORTRAN CHARACTER SET**

<table>
<thead>
<tr>
<th>Alphabetic</th>
<th>A to Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numeric</td>
<td>0 to 9</td>
</tr>
<tr>
<td>Special</td>
<td></td>
</tr>
<tr>
<td>=</td>
<td>equal</td>
</tr>
<tr>
<td>+</td>
<td>plus</td>
</tr>
<tr>
<td>-</td>
<td>minus</td>
</tr>
<tr>
<td>*</td>
<td>asterisk</td>
</tr>
<tr>
<td>/</td>
<td>slash</td>
</tr>
<tr>
<td>(</td>
<td>left parenthesis</td>
</tr>
<tr>
<td>)</td>
<td>right parenthesis</td>
</tr>
<tr>
<td>,</td>
<td>comma</td>
</tr>
<tr>
<td>.</td>
<td>decimal point</td>
</tr>
<tr>
<td>$</td>
<td>dollar sign</td>
</tr>
<tr>
<td>blank</td>
<td></td>
</tr>
<tr>
<td>≠</td>
<td>≠ or '</td>
</tr>
<tr>
<td>quote</td>
<td></td>
</tr>
</tbody>
</table>

In addition, any of the SCOPE set may be used in Hollerith constants and in comments. Blanks are not significant except in Hollerith fields.
FORTRAN STATEMENTS

<table>
<thead>
<tr>
<th>Column 1</th>
<th>C or $ or * indicates comment line</th>
</tr>
</thead>
<tbody>
<tr>
<td>Columns 1-2</td>
<td>CS indicates debug statement</td>
</tr>
<tr>
<td>Columns 1-5</td>
<td>Statement label</td>
</tr>
<tr>
<td>Column 6</td>
<td>Any character other than blank or zero denotes continuation; does not apply to comment cards. A debug continuation card must contain CS in columns 1-2.</td>
</tr>
<tr>
<td>Columns 7-72</td>
<td>Statement</td>
</tr>
<tr>
<td>Columns 73-80</td>
<td>Identification field, not processed by compiler</td>
</tr>
</tbody>
</table>

CONTINUATION

Statements are coded in columns 7-72; if a statement is longer than 66 columns, it may be continued on as many as 19 lines. A character other than blank or zero in column 6 indicates a continuation line. Column 1 can contain any character other than C *, or $; columns 2, 3, 4 and 5 may contain any character. Any statement except a comment, END or OVERLAY may be continued.

STATEMENT SEPARATOR

Several short statements may be written on one line if each is separated by the special character $. The statement following the $ sign is treated as a separate statement. For example:

```
7
ACUM = 24.
$I = 0
$IDIFF = 1970-1626
```

is the same as

```
7
ACUM = 24.$I = 0 $IDIFF = 1970-1626
```

$ may be used with all statements except FORMAT, OVERLAY, or debug statements. The statement following $ must not be labeled; the information following $ is treated exactly as if it were punched into column 7 on a succeeding card.

STATEMENT LABELS

Columns 1-5 of the first line of a statement may be used for the statement label. All executable statements (except END) may be labeled. Statements referenced by other statements must be labeled. Statement labels are integers 1-99999, and they may appear in any order. Leading zeros and leading or embedded blanks are not significant. Each statement label must be unique to the program unit in which it appears. In figure 1, statement labels are 4, 1, 2, and 3.
<table>
<thead>
<tr>
<th>STATEMENT NO.</th>
<th>CONT.</th>
<th>0 = ZERO</th>
<th>1 = ONE</th>

</tr>
</tbody>
</table>

Figure 1. Program PASCAL
COMMENTS

In column 1 a C, *, or $ indicates a comment line. Comments do not affect the program; they can be written in column 2 to 80 and can be placed anywhere within the program. If a comment occupies more than one line, each line must begin with C, *, or $ in column 1. The continuation character in column 6 does not apply to comment cards. Comments can appear between continuation cards.

COLUMNS 73-80

Any information may appear in columns 73-80 as they are not part of the statement. Entries in these columns are copied to the source program listing, but they are not processed by the compiler. They are generally used to order the punched cards in a deck.

BLANK CARDS

If blank cards are used to separate statements, they will produce a blank line on the source listing. A line following a blank card is treated as a new statement; therefore continuation cards must not follow blank cards.

A blank card should not follow the END statement. If it does an informative diagnostic is printed.

DATA CARDS

No restrictions are imposed on the format of data cards read by the source program. Data can be written in columns 1-80. Columns 73-80 are not ignored on data cards.
CONSTANTS AND VARIABLES

CONSTANTS

A constant is a fixed quantity. The seven types of constants are: integer, real, double precision, complex, octal, Hollerith, and logical.

INTEGER CONSTANT

\[ n_1 n_2 \ldots n_m \]

\[ 1 \leq m \leq 18 \text{ decimal digits} \]

Examples:

\[ 237 \quad -74 \quad +136772 \quad 0 \quad -0024 \]

An integer constant is a string of 1-18 decimal digits written without a decimal point. It may be positive, negative or zero. If the integer is positive, the plus sign may be omitted; if it is negative, the minus sign must be present. An integer constant must not contain a comma. The range of an integer constant is \(-2^{39} - 1\) to \(2^{39} - 1\) (\(2^{39} - 1 = 576\,460\,752\,303\,423\,487\)).

Examples of invalid integer constants:

\[ 48. \quad \text{(decimal point not allowed)} \]

\[ 23A \quad \text{(letter not allowed)} \]

\[ 7,200 \quad \text{(comma not allowed)} \]

When the integer constant is used as a subscript, or as the index in a DO statement or an implied DO, the maximum value is \(2^{17} - 2\) (\(2^{17} - 2 = 131\,070\)), and minimum is 1.

Integers used in multiplication and division are truncated to 48 bits. The result of integer multiplication or division will be less than \(2^{48} - 1\). If the result is larger than \(2^{48} - 1\), \((2^{48} - 1 = 281\,474\,976\,710\,655\)) high order bits will be lost. No diagnostic is provided. The resultant maximum value of conversion from real to integer or integer to real is \(2^{48} - 1\). If the value exceeds \(2^{48} - 1\), high order bits are lost; no diagnostic is provided. For addition and subtraction, the full 60-bit word is used.
REAL CONSTANT

<table>
<thead>
<tr>
<th>n.n</th>
<th>n.</th>
<th>n.nE±s</th>
<th>.nE±s</th>
<th>n.E±s</th>
<th>nE±s</th>
</tr>
</thead>
</table>

n          Coefficient ≤ 15 decimal digits
E±s        Exponent
s          Base 10 scale factor

A real constant consists of a string of decimal digits written with a decimal point or an exponent, or both. Commas are not allowed. If positive, a plus sign is optional.

The range of a real constant is $10^{-308}$ to $10^{+308}$; if this range is exceeded, a diagnostic is printed. Precision is approximately 14 decimal digits, and the constant is stored internally in one computer word.

Examples:

7.5  -3.22  +4000.  23798.14  .5  -.72  42.E1  700.E-2

Examples of invalid real constants:

3,50.  (comma not allowed)
2.5A   (letter not allowed)

A real constant may be followed by a decimal exponent, written as the letter E and an integer constant indicating the power of ten by which the number is to be multiplied. The field following the letter E may be zero, but it must not be omitted. The sign may be omitted if the exponent is positive, but it must be present if the exponent is negative. The range of the integer exponent is -308 through +337.

Examples:

42.E1   $(42. \times 10^1 = 420.)$
.00028E+5 $(0.00028 \times 10^5 = 28.)$
6.205E12 $(6.205 \times 10^{12} = 6205000000000.)$
8.0E+6  $(8. \times 10^6 = 8000000.)$
700.E-2 $(700. \times 10^{-2} = 7.)$
7E20    $(7. \times 10^{20} = 7000000000000000000.)$

Example of invalid real constants:

7.2E3.4 exponent not an integer
DOUBLE PRECISION CONSTANT

\[ n.nD^\pm s \quad .nD^\pm s \quad n.D^\pm s \quad nD^\pm s \]

n          Coefficient
D ± s      Exponent
s          Base 10 scale factor

Double precision constants are written in the same way as real constants except the exponent is specified by the letter D instead of E. Double precision values are represented internally by two computer words, giving extra precision. A double precision constant is accurate to approximately 29 decimal digits.

Examples:

5.834D2 \quad (5.834 \times 10^2 = 583.4)
14.D-5 \quad (14. \times 10^{-5} = .00014)
9.2D03 \quad (9.2 \times 10^3 = 9200.)
-7.D2 \quad (-7. \times 10^2 = -700.)
3120D4 \quad (3120. \times 10^4 = 31200000.)

Examples of invalid double precision constants:

7.2D \quad exponent missing
D5 \quad exponent alone not allowed
2,1.3D2 \quad comma illegal
3.141592653589793238462643383279 \quad D missing
COMPLEX CONSTANT

\[(r1, r2)\]

\begin{align*}
  r1 & \quad \text{Real part} \\
  r2 & \quad \text{Imaginary part}
\end{align*}

Each part has the same range as a real constant.

Complex constants are written as a pair of real constants separated by a comma and enclosed in parentheses.

<table>
<thead>
<tr>
<th>FORTRAN Coding</th>
<th>Complex Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1., 7.54)</td>
<td>1. + 7.54i</td>
</tr>
<tr>
<td>(-2.1E1, 3.24)</td>
<td>-21. + 3.24i</td>
</tr>
<tr>
<td>(4.0, 5.0)</td>
<td>4.0 + 5.0i</td>
</tr>
<tr>
<td>(0., -1.)</td>
<td>0.0 - 1.0i</td>
</tr>
</tbody>
</table>

The first constant represents the real part of the complex number, and the second constant represents the imaginary part. The parentheses are part of the constant and must always appear. Either constant may be preceded by a plus or minus sign. Complex values are represented internally by two consecutive computer words.

Both parts of complex constants must be real; they may not be integer.

Examples of invalid complex constants:

\begin{align*}
  (275, 3.24) & \quad 275 \text{ is an integer} \\
  (12.7D-4 16.1) & \quad \text{comma missing and double precision not allowed} \\
  4.7E+2,1.942 & \quad \text{parentheses missing} \\
  (0,0) & \quad 0 \text{ is an integer}
\end{align*}

Real constants which form the complex constant may range from \(10^{-93}\) to \(10^{+322}\).
OCTAL CONSTANT †

\[ n_1 \ldots n_mB \]

\[ n \leq m \leq 20 \text{ octal digits} \]

An octal constant consists of 1 to 20 octal digits suffixed with the letter B.

Examples:

\[ 777777B \]
\[ 52525252B \]
\[ 500127345B \]

Invalid octal constants:

\[ 892777B \] 8 and 9 are non-octal digits
\[ 77000000007777752525252B \] exceeds 20 digits
\[ 07766 \] O not allowed

An octal constant must not exceed 20 digits nor contain a non-octal digit. If it does, a fatal compiler diagnostic is printed. When fewer than 20 octal digits are specified, the digits are right justified and zero filled. Octal constants can be used anywhere integer constants can be used, except: they cannot be used as statement labels or statement label references, in a FORMAT statement, or as the character count when a Hollerith constant is specified.

They can be used in DO statements, expressions, and DATA statements, and as DIMENSION specifications.

Examples:

\[ \text{BAT} = (I*5252B) \text{.OR. JAY} \] masking expression
\[ J = \text{MAXO} (I,1000B,J,K+40B) \] octal constant used as parameter in function
\[ \text{NAME} = I \text{.AND. 77700000B} \] masking expression
\[ J = (5252B + N)/K \] arithmetic expression
\[ \text{DIMENSION BUF}(1000B) \] dimension specification

When an octal constant is used in an expression, it assumes the type of the dominant operand of the expression (Table 3-1, section 3).

†Blue type indicates non-ANSI statements.
HOLLERITH CONSTANTS

<table>
<thead>
<tr>
<th>nHf</th>
<th>nLf</th>
<th>nRf</th>
<th>( \neq f \neq )</th>
</tr>
</thead>
</table>

- **n**: Unsigned decimal integer representing number of characters in string. Must be greater than zero, and not more than 10 when used in an expression.
- **f**: String of characters
- **\( \neq f \neq \)**: String delimiters
- **H**: Left justified with blank fill
- **L**: Left justified with binary zero fill
- **R**: Right justified with binary zero fill

```plaintext
5 7
PROGRAM HOLL (CUTPUT)
A = 6HARCODEF
F = 6LARCODEF
C = 6RARCODEF
D = #ARCODEF#
PRINT 1, A,A,E,R,C,C,C,D
FORMAT (O24,A15)
STCF
END
```

**Stored Internally:**

1. 012030405065555555
2. 012030415060000000
3. 00000000010707040506
4. 012030405065555555

**Display Code:**

1. A
2. B
3. C
4. D
A Hollerith constant consists of an unsigned decimal integer, the letter H, and a string of characters. For example:

```
5HLABEL
```

The integer represents the number of characters in the string. Spaces are significant in a Hollerith constant:

```
18HTHIS IS A CONSTANT
7HTHE END
19HRESULT NUMBER THREE
```

```
I = (+5HABCDE) is a valid statement; (+5HABCDE) is an expression and the + sign is an operator.
```

Hollerith constants may be used in arithmetic expressions, DATA and FORMAT statements, as arguments in subprogram calls, and as list items in an output list of an input/output statement. If a Hollerith constant is used as an operand in an arithmetic operation, an informative diagnostic is given. In an expression or a DATA statement, a Hollerith constant is limited to 10 characters. In a FORMAT statement or as an actual argument to a subprogram, the length of the Hollerith string is limited to 150 characters.

A Hollerith string delimited by the paired symbols ≠ ≠ can be used anywhere the H form of the Hollerith constant can be used. For example,

```
IF(Y.EQ.≠YES≠) Y=Y+1.
PRINT 1, ≠ SQRT = ≠, SQRT(4.)
PRINT 2, ≠ TEST PASSED ≠
INTEGER LINE(7), N1THRU9
LOGICAL NEWPAGE
IF (NEWPAGE) LINE(7) = ≠ PAGE 0 ≠ + N1 THRU 9

PROGRAM FL(OUTPUT)
PRINT 1, ≠ FIELD LENGTH ≠ ≠, IGETFL(I)
1 FORMAT (2A10, I6)
END
```
The symbol ≠ can be represented within the string by two successive ≠ symbols.

When the number of characters in a Hollerith constant is less than 10, the computer word is left justified with blank fill. If it is more than 10, but not a multiple of 10, only the last computer word is left justified with blank fill.

Examples:

```
    7
  READ 1,NAME
  1 FORMAT (A7)
  IF(NAME .EQ. 4HJOAN) GO TO 20

    7
1000 WRITE (6,1000)
1000 FORMAT (1X, 73H NO COUNTRY THAT HAS BEEN THOROUGHLY Explored is
                   INFESTED WITH DRAGONS.)
```

nrf and nlf

A Hollerith constant of the form R or L is limited to 10 characters and cannot be used in a FORMAT statement.

LOGICAL CONSTANTS

A logical constant takes the forms:

- .TRUE. or .T. representing the value true
- .FALSE. or .F. representing the value false

The decimal points are part of the constant and must appear.
Examples:

PROGRAM LOGIC(INPUT,OUTPUT,TAPE5=INPUT)
   LOGICAL MALE, PHD, SINGLE, ACCEPT
   INTEGER AGE
PRINT 20
FORMAT (*1 LIST OF ELIGIBLE CANDIDATES*)
READ (5,1) LNAME, FNAME, MALE, PHD, SINGLE, AGE
FORMAT (2A10,3L5,I2)
   IF (EOF(5)) 6,4
   ACCEPT = MALE .AND. PHD .AND. SINGLE .AND. (AGE .GT. 25 .AND. 
   AGE .LT. 45)
   IF (ACCEPT) PRINT 2, LNAME, FNAME, AGE
   FORMAT (1H0,2A10,3X,I2)
   GO TO 3
STOP
END

(An explanation of this example appears in part 2.)

LOGICAL X1, X2
.
.
.
X1 = .TRUE.
X2 = .FALSE.

VARIABLE NAMES

Unless otherwise stated, the term variable applies to both Large Core Memory (LCM) and Small Core Memory (SCM) variables.†

A variable represents a quantity whose value may vary; this value may change repeatedly during program execution. Variables are identified by a symbolic name of 1-7 alphanumeric characters, the first of which must be alphabetic. A variable is associated with a storage location; and whenever the variable is used, it assumes the value currently in that location. The five types of variables are: logical, integer, real, double precision and complex.

The type of a variable is implied by its first character if it is not defined explicitly with a type declaration (section 5). If type is not declared, a variable is type integer if the first character of the symbolic name is I, J, K, L, M or N, and if no IMPLICIT statement appears in that program unit.

†Red type applies to 7600 computer and CYBER 70 Model 76.
Examples:

```
I0RM    JINZ2   KODE   NEXT23   M
```

A variable not defined in a type declaration is type real if the first character of the symbolic name is any letter other than I, J, K, L, M, N, and if no IMPLICIT statement appears in that program unit.

Examples:

```
RESULT   ASUM   A73   BOX
```

### Implied Typing of Variables

<table>
<thead>
<tr>
<th>A-H, O-Z</th>
<th>Real</th>
</tr>
</thead>
<tbody>
<tr>
<td>I-N</td>
<td>Integer</td>
</tr>
</tbody>
</table>

### INTEGER VARIABLE

An integer variable name must be 1-7 alphanumeric characters; the first letter must be I, J, K, L, M, or N if the type has not been defined explicitly.

The value range is $-2^{59} \cdot 1$ to $2^{59} \cdot 1$. When an integer variable is used as a subscript or as the index in a DO statement, the maximum value is $2^{17} \cdot 2$. The resultant absolute value of conversion from integer to real, integer multiplication, integer division, or input/output under the I format specification must be less than $2^{48} \cdot 1$. If this value is exceeded, high order bits will be lost. The resultant absolute value of integer addition or subtraction must be less than $2^{59} \cdot 1$.

Examples:

```
ITEM1   NSUM   JSUM   N72   J   K2504
```

### REAL VARIABLES

A real variable name must be 1-7 alphanumeric characters of which the first must be any letter other than I, J, K, L, M, or N if the type has not been defined explicitly.

The value range is $10^{-203}$ to $10^{+372}$, with approximately 14 significant digits.

Examples:

```
AVAR    SUM3   RESULT   TOTAL2   BETA    XXXX
```
DOUBLE PRECISION VARIABLES

Double precision variable names must be defined explicitly by a type declaration. The value of a double precision variable may range from $10^{-293}$ to $10^{+322}$, with approximately 29 significant digits.

Example:

    DOUBLE PRECISION OMEGA, X, IOTA

COMPLEX VARIABLES

Complex variables must be defined explicitly by a type declaration. A complex variable occupies two words in storage. Each word contains a number in real variable format, and each number can range from $10^{-293}$ to $10^{+322}$.

Example:

    COMPLEX ZETA, MU, LAMBDA

LOGICAL VARIABLES

Logical variables must be defined explicitly by a type declaration. A logical variable has the value true or false. A logical variable with a positive zero value is false; any other value is true.

Example:

    LOGICAL L33, PRAVDA, VALUE

OCTAL AND HOLLERITH DATA

Octal and Hollerith data can be entered or used in any type variable. When an octal or Hollerith constant is used in an arithmetic operation, it needs no conversion. If the constant is not combined with another type of variable or constant, it is considered to be of integer type.
Examples:

```
JX = 7HA0COUNT
JX is an integer variable containing a Hollerith constant.

IIT = 357215B
IIT is an integer variable containing an octal constant.

BC = 174B - 623B
For addition, octal constants are treated as two integer constants: the result
is converted to the type defined for BC and stored.

KLM = 3.14 - 35B
KLM is defined as integer. The octal constant assumes the type of the other
operand (real) and the result, which is real, is converted to integer before
being stored in KLM.
```

ARRAYS

A FORTRAN array is a set of elements identified by a single name. A particular element in the array may
be referenced by its position in the array. Arrays may have one, two, or three dimensions; the array name
and dimensions must be declared in a DIMENSION, COMMON or type declaration.

Example:

```
PROGRAM VANDIM (OUTPUT*TAPE6=OUTPUT)
COMMON X(4*3)
REAL Y(6)
CALL IOTA(X*12)
CALL IOTA(Y*6)
WRITE (6*100) X*Y
190 FORMAT (91ARRAY X = '12F6.0,5X,91ARRAY Y = '6F6.0)
STOP
END
```

The number of elements in an array is the product of the dimensions. For example, STOR(3,7) contains 21
elements. STOR(6,6,3) contains 108. The number of subscripts must not exceed the number specified in
the array declaration. For example, a one dimensional array A(I) cannot be referred to as A(I,J) and a two
dimensional array A(I,J) cannot be referred to as A(I,J,K). Such references would produce a diagnostic.

The number of dimensions in the array is indicated by the number of subscripts in the declaration.

```
DIMENSION STOR(6) declares a one-dimensional array of six elements

REAL STOR(3,7) declares a two-dimensional array of three rows and seven columns

LOGICAL STOR(6,6,3) declares a three-dimensional array of six rows, six columns and three planes
```

Each element in the array is referred to by the array name followed by a set of expressions in parentheses,
called subscripts. Subscripts indicate the position of the element in the array.
Example:

The array N consists of six values in the order: 10, 55, 11, 72, 91, 7

N(1) value 10
N(2) value 55
N(3) value 11
N(4) value 72
N(5) value 91
N(6) value 7

The entire array may be referenced by the unsubscripted array name when it is used as an item in an input/output list or in a DATA statement. In an EQUIVALENCE statement, however, only the first element of the array is implied by the unsubscripted array name.

Example:

The two-dimensional array TABLE (4,3) has four rows and three columns.

<table>
<thead>
<tr>
<th>Column 1</th>
<th>Column 2</th>
<th>Column 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row 1</td>
<td>44</td>
<td>10</td>
</tr>
<tr>
<td>Row 2</td>
<td>72</td>
<td>20</td>
</tr>
<tr>
<td>Row 3</td>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>Row 4</td>
<td>91</td>
<td>76</td>
</tr>
</tbody>
</table>

To refer to the number in row two, column three write TABLE(2,3).

\[
\text{TABLE}(3,3) = 30 \quad \text{TABLE}(1,1) = 44 \quad \text{TABLE}(4,1) = 91
\]

\[
\text{TABLE}(4,4) \text{ would be outside the bounds of the array and results may be unpredictable.}
\]

Zero and negative subscripts are not allowed. If the number of subscripts in a reference is less than the declared dimensions, the compiler assumes missing subscripts have a value of one.
For example, in an array $A(I,J,K)$

$A(I,J)$ implies $A(I,J,1)$

$A(I)$ implies $A(I,1,1)$

$A$ implies $A(1,1,1)$

Similarly for $A(I,J)$

$A(I)$ implies $A(I,1)$

$A$ implies $A(1,1)$

and for $A(I)$

$A$ implies $A(1)$

For example, in a three-dimensional array $\text{NEXT}$ when only one subscript is shown, the remaining subscripts are assumed to be one.

<table>
<thead>
<tr>
<th>Plane 1</th>
<th>Plane 2</th>
<th>Plane 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Col 1</td>
<td>Col 2</td>
<td>Col 3</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
<tr>
<td>0</td>
<td>33</td>
<td>2</td>
</tr>
<tr>
<td>22</td>
<td>51</td>
<td>7</td>
</tr>
<tr>
<td>0</td>
<td>98</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>207</td>
<td>99</td>
</tr>
</tbody>
</table>

Row 1  | Row 2  | Row 3  |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>1</td>
<td>552</td>
</tr>
<tr>
<td>77</td>
<td>60</td>
<td>3</td>
</tr>
<tr>
<td>85</td>
<td>100</td>
<td>8</td>
</tr>
</tbody>
</table>

†Except in input/output lists, as arguments to functions or subroutines, and DATA statements.
ARRAY STRUCTURE

Arrays are stored in ascending locations; the value of the first subscript increases most rapidly, and the value of the last increases least rapidly.

Example:

In an array declared as $A(3,3,3)$, the elements of the array are stored by columns in ascending locations.
The array is stored in linear sequence as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Location Relative to first Element</th>
</tr>
</thead>
<tbody>
<tr>
<td>A(1,1,1)</td>
<td>stored in 0</td>
</tr>
<tr>
<td>A(2,1,1)</td>
<td></td>
</tr>
<tr>
<td>A(3,1,1)</td>
<td></td>
</tr>
<tr>
<td>A(1,2,1)</td>
<td></td>
</tr>
<tr>
<td>A(2,2,1)</td>
<td></td>
</tr>
<tr>
<td>A(3,2,1)</td>
<td></td>
</tr>
<tr>
<td>A(1,3,1)</td>
<td></td>
</tr>
<tr>
<td>A(2,3,1)</td>
<td></td>
</tr>
<tr>
<td>A(3,3,1)</td>
<td></td>
</tr>
<tr>
<td>A(1,1,2)</td>
<td></td>
</tr>
<tr>
<td>A(2,1,2)</td>
<td></td>
</tr>
<tr>
<td>A(3,1,2)</td>
<td></td>
</tr>
<tr>
<td>A(1,2,2)</td>
<td></td>
</tr>
<tr>
<td>A(2,2,2)</td>
<td></td>
</tr>
<tr>
<td>A(3,2,2)</td>
<td></td>
</tr>
<tr>
<td>A(1,3,2)</td>
<td></td>
</tr>
<tr>
<td>A(2,3,2)</td>
<td></td>
</tr>
<tr>
<td>A(3,3,2)</td>
<td></td>
</tr>
<tr>
<td>A(1,1,3)</td>
<td></td>
</tr>
<tr>
<td>A(2,1,3)</td>
<td></td>
</tr>
<tr>
<td>A(3,1,3)</td>
<td></td>
</tr>
<tr>
<td>A(1,2,3)</td>
<td></td>
</tr>
<tr>
<td>A(2,2,3)</td>
<td></td>
</tr>
<tr>
<td>A(3,2,3)</td>
<td></td>
</tr>
<tr>
<td>A(1,3,3)</td>
<td></td>
</tr>
<tr>
<td>A(2,3,3)</td>
<td></td>
</tr>
<tr>
<td>A(3,3,3)</td>
<td></td>
</tr>
</tbody>
</table>

To find the location of an element in the linear sequence of storage locations the following method can be used:

<table>
<thead>
<tr>
<th>Number of Dimensions</th>
<th>Array Dimension</th>
<th>Subscript</th>
<th>Location of Element Relative to Starting Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ALPHA(K)</td>
<td>ALPHA(k)</td>
<td>(k-1)XE</td>
</tr>
<tr>
<td>2</td>
<td>ALPHA(K,M)</td>
<td>ALPHA(k,m)</td>
<td>(k+1+MX(m-1))XE</td>
</tr>
<tr>
<td>3</td>
<td>ALPHA(K,M,N)</td>
<td>ALPHA(k,m,n)</td>
<td>(k+1+MX(m-1+MX(n-1)))XE</td>
</tr>
</tbody>
</table>

Figure 2-1. Array Element Location

K, M, and N are dimensions of the array.
k,m, and n are the actual subscript values of the array.
1 is subtracted from each subscript value because the subscript starts with 1, not 0.

E is length of the element. For real, logical, and integer arrays, \( E = 1 \). For complex and double precision arrays, \( E = 2 \).

Examples:

<table>
<thead>
<tr>
<th>INTEGER ALPHA (3)</th>
<th>Subscript</th>
<th>Location of Element Relative to Starting Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALPHA(2)</td>
<td></td>
<td>((2-1 = 1))</td>
</tr>
<tr>
<td>REAL ALPHA (3,3)</td>
<td>ALPHA(3,1)</td>
<td>((3-1+3\times(1-1))\times1 = 2)</td>
</tr>
<tr>
<td>REAL ALPHA (3,3,3)</td>
<td>ALPHA(3,2,1)</td>
<td>((3-1+3\times(2-1)+3\times3\times(1-1))\times1 = 5)</td>
</tr>
</tbody>
</table>

A single subscript may be used for an array with multiple dimensions.

The amount of storage allocated to arrays is discussed under DIMENSION declarations in Section 5.

**SUBSCRIPTS**

A subscript can be any valid arithmetic expression. If the value of the expression is not integer, it is truncated to integer.

The value of the subscript must be greater than zero and less than or equal to the maximum specified in the array specification statement, or the reference will be outside the array. If the reference is outside the bounds of the array, results are unpredictable.

Examples:

Valid subscripts:

- A(1,K)
- B(I+2,J-3,6*K+2)
- LAST(6)
- ARAYD(1,3,2)
- STRING(3*K*ITEM+3)

Invalid subscripts:

- ATLAS(0) zero subscript not allowed
- D(1 .GE. K) relational or logical expression illegal
- Z14(-4) negative subscript not allowed
FORTRAN expressions are arithmetic, masking, logical and relational. Arithmetic and masking expressions yield numeric values, and logical and relational expressions yield truth values.

**ARITHMETIC EXPRESSIONS**

An arithmetic expression is a sequence of unsigned constants, variables, and function references separated by operators and parentheses. For example,

\[(A-B)*F+C/D**E\] is a valid arithmetic expression

FORTRAN arithmetic operators:

- `+` addition
- `-` subtraction
- `*` multiplication
- `/` division
- `**` exponentiation

An arithmetic expression may consist of a single constant, variable, or function reference. If \(X\) is an expression, then \((X)\) is an expression. If \(X\) and \(Y\) are expressions, then the following are expressions:

\[X+Y\]
\[X-Y\]
\[X*Y\]
\[X/Y\]
\[-X\]
\[X**Y\]
\[+X\]
All operations must be specified explicitly. For example, to multiply two variables A and B, the expression A*B must be used. AB, (A)(B), or A*B will not result in multiplication.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Value of</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.78542</td>
<td>Real constant 3.78542</td>
</tr>
<tr>
<td>A(2*J)</td>
<td>Array element A (2*J)</td>
</tr>
<tr>
<td>BILL</td>
<td>Variable BILL</td>
</tr>
<tr>
<td>SQRT(5.0)</td>
<td>$\sqrt{5}.$</td>
</tr>
<tr>
<td>A+B</td>
<td>Sum of the values A and B</td>
</tr>
<tr>
<td>C*D/E</td>
<td>Product of C times D divided by E</td>
</tr>
<tr>
<td>J**I</td>
<td>Value of J raised to the power of I</td>
</tr>
<tr>
<td>(200 - 50)**2</td>
<td>300</td>
</tr>
</tbody>
</table>

**EVALUATION OF EXPRESSIONS**

The precedence of operators for the evaluation of expressions is shown below:

```
**                (exponentiation)
/     *           (division or multiplication)
+     -           (addition or subtraction).
.GT.  .GE. .LT.  .LE.  .EQ.  .NE. (relationals)
.NOT.                (logical)
.AND.                (logical)
.OR.                 (logical)
```

Unary addition or subtraction are treated as operations on an implied zero. For example, +2 is treated as 0+2, -3 is treated as 0-3.

Expressions are evaluated from left to right with the precedence of the operators and parentheses controlling the sequence of operation (the deepest nested parenthetical subexpression is evaluated first).

However, any function references and exponentiation operations not evaluated inline are evaluated prior to other operations.

In an expression with no parentheses or within a pair of parentheses in which unlike classes of operators appear, evaluation proceeds in the above order. In expressions containing like classes of operators, evaluation proceeds from left to right A**B**C is evaluated as ((A**B)**C).
An array element name (a subscripted variable) used in an expression requires the evaluation of its subscript. The type of the expression in which a function reference or subscript appears does not affect, nor is it affected by the evaluation of the arguments or subscripts.

The evaluation of an expression having any of the following conditions is undefined:

- Negative-value quantity raised to a real, double precision, or complex exponent
- Zero-value quantity raised to a zero-value exponent
- Infinite or indefinite operand (section 4, part 3)
- Element for which a value is not mathematically defined, such as division by zero

If the error traceback option is selected on the FTN control card (section 11), the first three conditions will produce informative diagnostics during execution. If the traceback option is not selected, a mode error message is printed (section 4, part 3).

Two operators must not be used together. A*'-B and Z/+'+X are not allowed. However, a unary + or - can be separated from another operator in an expression by using parentheses. For example,

\[
\begin{align*}
A^*(-B) & \text{ and } Z/(+X) \quad \text{Valid expressions} \\
B^*=-A & \text{ and } X/-Y^*Z \quad \text{Invalid expressions}
\end{align*}
\]

Each left parenthesis must have a corresponding right parenthesis.

Example:

\[
(F + (X * Y)) \quad \text{Incorrect, right parenthesis missing}
\]

\[
(F + (X * Y)) \quad \text{Correct}
\]

Examples:

In the expression A-B*C

B is multiplied by C, and the product is subtracted from A.

The expression A/B-C*D**E is evaluated as:

- D is raised to the power of E.
- A is divided by B.
- C is multiplied by the result of D**E.

The product of C*D**E is subtracted from the quotient of A divided by B.

The expression -A**C is evaluated as 0-A**C; A is first raised to the power of C and the result is then subtracted from zero.
An expression containing operators of equal precedence is evaluated from left to right.

\[ A/B/C \]

A is divided by B, and the quotient is divided by C. \((A/B)/C\) is an equivalent expression.

The expression \(A**B**C\) is, in effect, \(((A**B)**C)\).

Dividing an integer by another integer yields a truncated result; \(11/3\) produces the result 3. Therefore, when an integer expression is evaluated from left to right, \(J/K*I\) may give a different result than \(I*J/K\).

Example:

\[
\begin{align*}
I & = 4 & J & = 3 & K & = 2 \\
J/K*I & & I*J/K \\
3/2*4 & = 4 & 4*3/2 & = 6
\end{align*}
\]

An integer divided by an integer of larger magnitude yields the result 0.

Example:

\[
\begin{align*}
N & = 24 & M & = 27 & K & = 2 \\
N/M*K & \\
24/27*2 & = 0
\end{align*}
\]

Examples of valid expressions:

\[ A \]

\[ 3.14159 \]

\[ B + 16.427 \]

\[ (\bar{X} + (B(I,J+I,K) / 3.0)) \]

\[ -(C + \text{DELTA} \times \text{AERO}) \]

\[ (B - \text{SQRT}(B**2*(4*A*C))) / (2.0*A) \]

\[ \text{GROSS} - (\text{TAX} \times 0.04) \]

\[ \text{TEMP} + V(M, \text{MAXF}(A,B))**C / (\text{H-FACT}(K+3)) \]
TYPE OF ARITHMETIC EXPRESSIONS

An arithmetic expression may be of type integer, real, double precision, or complex. The order of dominance from highest to lowest is as follows:

Complex
Double Precision
Real
Integer

Table 3-1. Mixed Type Arithmetic Expressions

<table>
<thead>
<tr>
<th>1st operand</th>
<th>2nd operand</th>
<th>Hollerith</th>
<th>Integer</th>
<th>Real</th>
<th>Double Precision</th>
<th>Complex</th>
<th>Octal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hollerith</td>
<td>Integer</td>
<td>Integer</td>
<td>Real</td>
<td>Double Precision</td>
<td>Complex</td>
<td>Integer</td>

</tr>
<tr>
<td>Octal</td>
<td>Integer</td>
<td>Integer</td>
<td>Real</td>
<td>Double Precision</td>
<td>Complex</td>
<td>Integer</td>
<td></td>
</tr>
</tbody>
</table>

† Operators are + - * /

When an expression contains operands of different types, type conversion takes place during evaluation. Before each operation is performed, operands are converted to the type of the dominant operand. Thus the type of the value of the expression is determined by the dominant operand. For example, in the expression A*B-I/J, A is multiplied by B, I is divided by J as integer, converted to real, and subtracted from the result of A multiplied by B.
EXponentiation

In exponentiation, the following types of base and exponent are permitted:

<table>
<thead>
<tr>
<th>Base</th>
<th>Power</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>Integer, Real, Double Precision, Complex</td>
</tr>
<tr>
<td>Real</td>
<td>Integer, Real, Double Precision, Complex</td>
</tr>
<tr>
<td>Double Precision</td>
<td>Integer, Real, Double Precision, Complex</td>
</tr>
<tr>
<td>Complex</td>
<td>Integer</td>
</tr>
</tbody>
</table>

The exponent is evaluated from left to right. The expression A**B**C is, in effect, ((A**B)**C)

In an expression of the form A**B the type of the result is determined as follows:

<table>
<thead>
<tr>
<th>Type of A</th>
<th>Type of B</th>
<th>Type of Result of A**B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>Integer</td>
<td>Integer</td>
</tr>
<tr>
<td></td>
<td>Real</td>
<td>Real</td>
</tr>
<tr>
<td></td>

<td>Complex</td>
<td>Complex</td>
</tr>
<tr>
<td>Complex</td>
<td>Integer</td>
<td>Complex</td>
</tr>
</tbody>
</table>

The expression -2**2 is equivalent to 0-2**2. An exponent may be an expression. The following examples are all acceptable:

B**2. A negative exponent must be enclosed in parentheses:

B**N

B**(2*N-1)

(A+B)**(-J)
Examples:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>CVAB**(1-3)**</td>
<td>Real**Integer</td>
<td>Real</td>
</tr>
<tr>

<td>Integer**Integer</td>
<td>Integer</td>
</tr>
<tr>
<td>3.14D-02**5.14D-02</td>
<td>Double Precision</td>
<td>Double Precision</td>
</tr>
</tbody>
</table>

**RELATIONAL EXPRESSIONS**

\[
\begin{array}{c}
  a_1 \text{ op } a_2 \\
\end{array}
\]

- \(a_1, a_2\)  
  - Arithmetic or masking expression

- \(\text{op}\)  
  - Relational operator

A relational expression is constructed from arithmetic or masking expressions and relational operators. Arithmetic expressions may be type integer, real, double precision, or complex. The relational operators are:

- .GT.  
  - Greater than

- .GE.  
  - Greater than or equal to

- .LT.  
  - Less than

- .LE.  
  - Less than or equal to

- .EQ.  
  - Equal to

- .NE.  
  - Not equal to

The enclosing decimal points are part of the operator and must be present.
Two expressions separated by a relational operator constitute a basic logical element. The value of this element is either true or false. If the expressions satisfy the relation specified by the operator, the value is true; if not, it is false. For example:

\[ x+y \geq 5.3 \]

If \( x+y \) is greater than 5.3 the value of the expression is true. If \( x+y \) is less than or equal to 5.3 the value of the expression is false.

A relational expression can have only two operands combined by one operator. \( a_1 \ op \ a_2 \ op \ a_3 \) is not valid.

Relational operands may be of type integer, real, double precision, or complex, but not logical. With the exception of the relational operators .EQ. and .NE., only the real part of complex operands are used in evaluation.

Examples:

```
J.LT.ITEM
580.2 .GT. VAR
B .GE. (2.7, 5.9E3)
E.EQ..5
(I) .EQ. (J(K))
C.LT. 1.5D4
```

real part of complex number is used in evaluation

most significant part of double precision number is used in evaluation

**EVALUATION OF RELATIONAL EXPRESSIONS**

Relational expressions are evaluated according to the rules governing arithmetic expressions. Each expression is evaluated and compared with zero to determine the truth value. For example, the expression \( p.EQ.q \) is equivalent to the question, does \( p - q = 0 \)? \( q \) is subtracted from \( p \) and the result is tested for zero. If the difference is zero or minus zero the relation is true. Otherwise, the relation is false.

If \( p \) is 0 and \( q \) is -0 the relation is true.

Expressions are evaluated from left to right. Parentheses enclosing an operand do not affect evaluation; for example, the following relational expressions are equivalent:

```
A.GT.B
A.GT.(B)
(A).GT.B
(A).GT.(B)
```
Examples:

- REAL A
  A.GT.720
- AMT .LT. (1.,6.55)
- INTEGER I, J
  I.EQ.J(K)
- A+B.GE.Z**2
- (I).EQ.(N*J)
- 300.+B.EQ.A-Z
- B.LE.3.754
- Z.LT.35.3D+5
- .5+2. .GT. .8+AMNT

Examples of invalid expressions:

- A .GT. 720 .LE. 900 2 relational operators must not appear in a relational expression
- B .LE. 3.754 .EQ. C

**LOGICAL EXPRESSIONS**

\[ L_1 \text{ op } L_2 \text{ op } L_3 \text{ op } \ldots L_n \]

- \( L_1 \ldots L_n \) logical operand or relational expression
- \text{op} \hspace{1cm} \text{logical operator}

A logical expression is a sequence of logical constants, logical variables, logical array elements, or relational expressions separated by logical operators and possibly parentheses. After evaluation, a logical expression has the value true or false.

Logical operators:
- .NOT. or .N. logical negation
- .AND. or .A. logical multiplication
- .OR. or .O. inclusive OR

The enclosing decimal points are part of the operator and must be present.
The logical operators are defined as follows (p and q represent LOGICAL expressions):

_NOT_.p If p is true, _NOT_.p has the value false. If p is false, _NOT_.p has the value true.

p.AND.q If p and q are both true, p.AND.q has the value true. Otherwise, false.

p.OR.q If either p or q, or both, are true then p.OR.q has the value true. If both p and q are false, then p.OR.q has the value false.

<table>
<thead>
<tr>
<th>p</th>
<th>q</th>
<th>p .AND. q</th>
<th>p .OR. q</th>
<th><em>NOT</em>. p</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

If precedence is not established explicitly by parentheses, operations are executed in the following order:

_NOT_.

.AND.

.OR.
Example:

```fortran
PROGRAM LOGIC(INPUT,OLPUT,TAPES=INPUT)
LOGICAL MALE,FHD,SINGLE,ACCEPT
INTEGER AGE
PRINT 20
20 FORMAT (*1
LIST OF ELIGIBLE CANDIDATES*)
3 READ (5,1) LNAME,FNAME,MALE,FHD,SINGLE,AGE
1 FORMAT (2A10,3L5,I2)
IF (EOF(5))6,4
4 ACCEPT = MALE .AND. FHD .AND. SINGLE .AND. (AGE .GT. 25 .AND.
S = AGE .LT. 45)
IF (ACCEPT) PRINT 2, LNAME, FNAME, AGE
2 FORMAT (1HO,2A10,3X,I2)
GO TO 3
6 STOP
END
```

Data Cards:

```
RALPH        ERICSON    T    T    T      20
JOHN S.      SLIGHT     T    T    T      26
MILURED      MINSTER    F    T    T      41
JUSTIN       BROWN      T    T    T      30
JAMES        SMITH      T    F    T      27
```

Output:

```
LIST OF ELIGIBLE CANDIDATES

JOHN S. SLIGHT  26
JUSTIN BROWN    30
```
The operator .NOT. which indicates logical negation appears in the form:

`.NOT. p`

`.NOT. may appear in combination with .AND. or .OR. only as follows (p and q are logical expressions):`

`.p .AND..NOT. q`

`.p .OR..NOT. q`

`.p .AND.(.NOT. q )`

`.p .OR.(.NOT. q )`

`.NOT. may appear adjacent to itself only in the form .NOT(. NOT. (.NOT.p))`

Two logical operators may appear in sequence only in the forms .OR..NOT. and .AND..NOT.

Valid Logical Expressions:

```
LOGICAL M,L
.NOT.L
.NOT. (X .GT. Y)
X .GT. Y .AND. .NOT.Z
(L) .AND. M
```

Invalid Logical Expressions:

```
P,Q, and R are type logical

`.AND. P` .AND. must be preceded by a logical expression

`.OR. R` .OR. must be preceded by a logical expression

`.P .AND. .OR. R` .AND. always must be separated from .OR. by a logical expression
Examples:

A, X, B, C, J, L, and K are type logical.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Alternative Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>A .AND. .NOT. X</td>
<td>A .A. .N. X</td>
</tr>
<tr>
<td>.NOT. B</td>
<td>.N.B</td>
</tr>
<tr>
<td>A .AND. C</td>
<td>A .A.C</td>
</tr>
<tr>
<td>J .OR. L .OR. K</td>
<td>J.O.L.O.K</td>
</tr>
</tbody>
</table>

Examples:

\( B - C \leq A \leq B + C \) is written as \( B - C \ .LE. A \ .AND. A \ .LE. B + C \)

\( \text{FICA} > 176. \) and \( \text{PAYNB} = 5889. \) is written \( \text{FICA} \ .GT. 176. \ .AND. \text{PAYNB} \ .EQ. 5889. \)

**MASKING EXPRESSIONS**

Masking expressions are similar to logical expressions, but the elements of the masking expression are of any type variable, constant, or expression other than logical.

Examples:

\( J \ .AND. N \)  \( \ .NOT. (B) \)

\( .\NOT. 65 \)  \( \text{KAY .OR. 63} \)

Masking operators are identical in appearance to logical operators but meanings differ. In order of dominance from highest to lowest, they are:

\( \ .\NOT. \text{ or } .N. \)  Complement the operand

\( \ .\AND. \text{ or } .A. \)  Form the bit-by-bit logical product (AND) of two operands

\( \ .\OR. \text{ or } .O. \)  Form the bit-by-bit logical sum (OR) of two operands

The enclosing decimal points are part of the operator and must be present. Masking operators are distinguished from logical operators by non-logical operands.
Examples:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Alternative Form</th>
</tr>
</thead>
<tbody>
<tr>
<td>B .OR. D</td>
<td>B .O. D</td>
</tr>
<tr>
<td>A .AND. .NOT. C</td>
<td>A .A. .N. C</td>
</tr>
<tr>
<td>BILL .AND. BOB</td>
<td>BILL .A. BOB</td>
</tr>
<tr>
<td>I .OR. J .OR. K .OR. N</td>
<td>I .O. J .O. K .O. N</td>
</tr>
<tr>
<td>(.NOT. (.NOT. (.NOT. A .OR. B)))</td>
<td>(.N. (.N. (.N. A .OR. B)))</td>
</tr>
</tbody>
</table>

The operands may be any type variable, constant, or expression (other than logical).

Examples:

TAX .AND. INT
.NOT. 55
734 .OR. 82
A .AND. 77B
B .OR. C
M .AND. .NOT. 77B

Extract the low order 6 bits of A
Logical sum of the contents of B and C
Clear the low order 6 bits of M.

In masking operations operands are considered to have no type. If either operand is type COMPLEX, operations are performed only on the real part. If the operand is DOUBLE PRECISION only the most significant word is used. The operation is performed bit-by-bit on the entire 60-bit word. For simplicity, only 10 bits are shown in the following examples. Masking operations are performed as follows:

J = 0101011101 and I = 1100110101

J .AND. I

The bit-by-bit logical product is formed

J 0101011101
I 1100110101

0100010101 Result after masking

J .OR. I

The bit-by-bit logical sum is formed

J 0101011101
I 1100110101

1101111101 Result after masking
.NOT.  Complement the operand

.NOT. I
I 1100110101

                  Result after masking
0011001010

.NOT. may appear with .AND. and .OR. only as follows:

masking expression .AND. .NOT. masking expression

masking expression .OR. .NOT. masking expression

masking expression .AND. (.NOT. masking expression)

masking expression .OR. (.NOT. masking expression)

If an expression contains masking operators of equal precedence, the expression is evaluated from left to right.

A .AND. B .AND. C

A .AND. B is evaluated before B .AND. C

Using the following numbers:

A 777700000000000000000000 octal constant
D 000000007777777777 octal constant
B 00000000000000001763 octal form of integer constant
C 200450000000000000 octal form of real constant

Masking operations produce the following octal results:

. NOT. A is 00007777777777777

A .AND. C is 200400000000000000

A .AND. .NOT. C is 577300000000000000

B .OR. .NOT. D is 7777777700000001763

Invalid example:

LOGICAL A
A .AND. B .OR. C masking expression must not contain logical operand
Example:

```
PROGRAM MASK (INPUT, OUTPUT)
1 FORMAT (1H1, 5X, 4HNAME, //)
PRINT 1
2 FORMAT (3A10, I1)
3 READ 2, LNAME, FNAME, ISTATE, KSTOP
   IF (KSTOP .EQ. 1) STOP
   C IF FIRST TWO CHARACTERS OF ISTATE NOT EQUAL TO CA READ NEXT CARD
   IF ((ISTATE .AND. 777700000000000000B) .NE. (2HCA .AND. 777700000000000000B)) GO TO 3
11 FORMAT (5X, 2A10)
10 PRINT 11, LNAME, FNAME
   GO TO 3
END
```

An assignment statement evaluates an expression and assigns this value to a variable or array element. The statement is written as follows:

\[ v = \text{expression} \]

\( v \) is a variable or an array element

The meaning of the equals sign differs from the conventional mathematical notation. It means replace the variable on the left with the value of the expression on the right. For example, the assignment statement \( A = B + C \) replaces the current value of the variable \( A \) with the value of \( B + C \).

**ARITHMETIC ASSIGNMENT STATEMENTS**

\[ v = \text{arithmetic expression} \]

Replace the current value of \( v \) with the value of the arithmetic expression. The variable or array element can be any type other than logical.

Examples:

- \( A = A + 1 \) replace the value of \( A \) with the value of \( A + 1 \)
- \( N = J - 100 \times 20 \) replace \( N \) with the value of \( J - 100 \times 20 \)
- \( \text{WAGE} = \text{PAY} - \text{TAX} \) replace \( \text{WAGE} \) with the value of \( \text{PAY} \) less \( \text{TAX} \)
- \( \text{VAR} = \text{VALUE} + (7/4) \times 32 \) replace the value of \( \text{VAR} \) with the value of \( \text{VALUE} + (7/4) \times 32 \)
- \( B(4) = B(1) + B(2) \) replace the value of \( B(4) \) with the value of \( B(1) + B(2) \)
If the type of the variable on the left of the equals sign differs from that of the expression on the right, type conversion takes place. The expression is evaluated, converted to the type of the variable on the left, and then replaces the current value of the variable. The type of an evaluated arithmetic expression is determined by the type of the dominant operand. Below, the types are ranked in order of dominance from highest to lowest:

Complex

Double Precision

Real

Integer

In the following tables, if high order bits are lost by truncation during conversion, no diagnostic is given.

**CONVERSION TO INTEGER**

<table>
<thead>
<tr>
<th>Value Assigned</th>
<th>Example</th>
<th>Value of IFORM After Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Integer = Integer</strong></td>
<td>Value of integer expression replaces v.</td>
<td>IFORM = 10/2</td>
</tr>
<tr>
<td><strong>Integer = Real</strong></td>
<td>Value of real expression, truncated to 48-bit integer, replaces v.</td>
<td>IFORM = 2.5*2+3.2</td>
</tr>
<tr>
<td><strong>Integer = Double Precision</strong></td>
<td>Value of double precision expression, truncated to 48-bit integer, replaces v.</td>
<td>IFORM = 3141.593D3</td>
</tr>
<tr>
<td><strong>Integer = Complex</strong></td>
<td>Value of real part of complex expression truncated to 48-bit integer, replaces v.</td>
<td>IFORM = (2.5,3.0) + (1.0,2.0)</td>
</tr>
</tbody>
</table>
### CONVERSION TO REAL

<table>
<thead>
<tr>
<th>Value Assigned</th>
<th>Example</th>
<th>Value of AFORM After Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real = Integer</td>
<td>Value of integer expression, truncated to 48 bits, is converted to real and replaces v.</td>
<td>AFORM = 200 + 300</td>
</tr>
<tr>
<td>Real = Real</td>
<td>Value of real expression replaces v.</td>
<td>AFORM = 2.5 + 7.2</td>
</tr>
<tr>
<td>Real = Double Precision</td>
<td>Value of most significant part of expression replaces v.</td>
<td>AFORM = 3421.D – 04</td>
</tr>
<tr>
<td>Real = Complex</td>
<td>Value of real part of complex expression replaces v.</td>
<td>AFORM = (9.2,1.1) – (2.1,5.0)</td>
</tr>
</tbody>
</table>

### CONVERSION TO DOUBLE PRECISION

<table>
<thead>
<tr>
<th>Value Assigned</th>
<th>Example</th>
<th>Value of SUM After Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double Precision = Integer</td>
<td>Value of integer expression, truncated to 48 bits, is converted to real and replaces most significant part. Least significant part set to 0.</td>
<td>SUM = 7*5.0</td>
</tr>
<tr>
<td>Double Precision = Real</td>
<td>Value of real expression replaces most significant part; least significant part is set to 0.</td>
<td>SUM = 7.5*2</td>
</tr>
</tbody>
</table>
### CONVERSION TO DOUBLE PRECISION (CONTINUED)

<table>
<thead>
<tr>
<th>Value Assigned</th>
<th>Example</th>
<th>Value of SUM After Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double Precision = Double Precision</td>
<td>Value of double precision expression replaces v.</td>
<td>SUM = 7.322D2 - 32.D -1</td>
</tr>
<tr>
<td>Double Precision = Complex</td>
<td>Value of real part of complex expression replaces v. Least significant word is set to 0.</td>
<td>SUM = (3.2,7.6) + (5.5,1.0)</td>
</tr>
</tbody>
</table>

### CONVERSION TO COMPLEX

<table>
<thead>
<tr>
<th>Value Assigned</th>
<th>Example</th>
<th>Value of AFORM After Evaluation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complex = Integer</td>
<td>Value of integer expression, truncated to 48 bits, is converted to real, and replaces real part of v. Imaginary part is set to 0.</td>
<td>AFORM = 2 + 3</td>
</tr>
<tr>
<td>Complex = Real</td>
<td>Value of real expression replaces real part of v. Imaginary part set to 0.</td>
<td>AFORM = 2.3 + 7.2</td>
</tr>
<tr>
<td>Complex = Double Precision</td>
<td>Most significant part of double precision expression replaces real part of v. Imaginary part set to 0.</td>
<td>AFORM = 20D0 + 4.4D1</td>
</tr>
<tr>
<td>Complex = Complex</td>
<td>Value of complex expression replaces variable.</td>
<td>AFORM = (3.4,1.1) + (7.3,4.6)</td>
</tr>
</tbody>
</table>
LOGICAL ASSIGNMENT

Logical variable or array element = Logical or relational expression

Replace the current value of the logical variable or array element with the value of the expression.

Examples:

```
LOGICAL LOG2
I = 1
LOG2 = I .EQ. 0

LOG2 is assigned the value .FALSE. because I neq 0

LOGICAL NSUM,VAR
BIG = 200.
VAR = .TRUE.
NSUM = BIG .GT. 200. .AND. VAR

NSUM is assigned the value .FALSE.

LOGICAL A,B,C,D,E,LGA,LGB,LGC
REAL F,G,H
A = B .AND. C .AND. D
A = F .GT. G .OR. F .GT. H
A = .NOT. (A .AND. .NOT. B) .AND. (C .OR. D)
LGA = .NOT. LGB
LGC = E .OR. LGC .OR. LGB .OR. LGA .OR. (A .AND. B)
```

MASKING ASSIGNMENT

v = masking expression

Replace the value of v with the value of the masking expression. v can be any type other than logical. No type conversion takes place during replacement. If the type is double precision or complex, the value of the expression is assigned to the first word of the variable; and the least significant or imaginary part set to zero.

Examples:

```
B = D .AND. Z .OR. X
SUM = (1.0,2.0) .OR. (7.0,7.0)
NAME = INK .OR. JAY .AND. NEXT
J(3) = N .AND. I
A = (B.EQ.C) .OR. Z
```
INTEGER I,J,K,L,M,N(16)
REAL B,C,D,E,F(15)

N(2) = I.AND.J 
B = C.AND.L 
F(J) = I.OR..NOT.L.AND.F(J) 
I = .NOT.I 
N(1) = I.OR.J.OR.K.OR.L.OR.M

MULTIPLE ASSIGNMENT

\[ v_1 = v_2 = \ldots v_n = \text{expression} \]

Replace the value of several variables or array elements with the value of the expression. For example, 
\[ X = Y = Z = (10 + 2)/\text{SUM(1)} \] is equivalent to the following statements:

\[ Z = (10 + 2)/\text{SUM(1)} \]

\[ Y = Z \]

\[ X = Y \]

The value of the expression is converted to the type of the variable or array element during each replacement.

Examples:

\[ \text{NSUM} = \text{BSUM} = \text{ISUM} = \text{TOTAL} - 10.5 - 3.2 \]

1. TOTAL is assigned the value 7.3
2. ISUM is assigned the value 7
3. BSUM is assigned the value 7.0
4. NSUM is assigned the value 7

Multiple assignment is legal in all types of assignment statements.
FORTRAN statements are executed sequentially. However, the normal sequence may be altered with control statements.

ASSIGN          PAUSE
GO TO           STOP
IF              END
DO              RETURN
CONTINUE

Control may be transferred to an executable statement only; a transfer to a non-executable statement results in a fatal diagnostic. Compilation continues, but the program is not executable unless it is compiled in debug mode.

Statements are identified by an integer, 1-99999. Leading zeros are ignored. Each statement number must be unique in the program or subprogram in which it appears.

In the following control statements:

\[ \text{sn} = \text{statement label} \]
\[ \text{iv} = \text{integer variable} \]

**GO TO STATEMENT**

The three GO TO statements are: unconditional, computed, and assigned.
UNCONDITIONAL GO TO

Control transfers to the statement labeled sn.

Example:

```
10 A=B+Z
100 B=X+Y
   IF(A-B)20,20,30
20 Z=A
   GO TO 10  # Transfers control to statement 10
30 Z=B
STOP
END
```
30 if L = 3
20 if L = 4

The variable must not be specified by an ASSIGN statement. If it is specified by an ASSIGN statement, the object code is incorrect, but no compilation error message is issued.

If the value of the expression is less than 1, or larger than the number of statement numbers in parentheses, the transfer of control is undefined and a fatal error results. For example, execution of the following computed GO TO statement will cause a fatal error:

```
M=4
GO TO (100,200,300),M
```

Less than 4 numbers are specified in the list of statement numbers; therefore, the next statement to be executed is undefined.
Examples:

\begin{verbatim}
K=2  
GO TO(100,150,300)K  statement 150 will be executed next

K=2  
X=4.6  
. 
. 
. 
GO TO(10,110,11,12,13),X/K  control transfers to statement 110 since the integer part of the expression X/K equals 2

L = 7  
GO TO(35,45,20,10)L-5  statement 45 will be executed next.
. 
. 
. 
35 Z=R+X  
. 
. 
45 A=X+Y  
. 
. 
20 B=CAT**2  
. 
. 
10 ANS=RES+ERROR
\end{verbatim}

**ASSIGN STATEMENT**

![ASSIGN STATEMENT Diagram]

The value of iv is a statement label to which control may transfer. This statement is used in conjunction with the assigned GO TO statement. sn must be the label of an executable statement in the same program unit as the ASSIGN statement.
Example:

```
ASSIGN 10 TO LSWITCH
GO TO LSWITCH(5,10,15,20)    control transfers to statement 10
```

Once the integer variable, `iv`, is used in an ASSIGN statement, it must not be referenced in any statement, other than an assigned GO TO, until it has been redefined.

**ASSIGNED GO TO**

Example:

```
ASSIGN 50 TO CHOICE
10 GO TO CHOICE,(20,30,40,50)  statement 50 is executed immediately after statement 10
.
.
30 CAT=ZERO+HAT
.
.
40 CAT=10.1-3.
.
.
50 CAT=25.2+7.3
```

This statement transfers control to the statement label last assigned to the variable. The assignment must take place in a previously executed ASSIGN statement.

The comma after `iv` is optional. Omitting the list of statement labels `(sn_1,...,sn_m)` causes a fatal error. If the value of `iv` is defined by a statement other than an ASSIGN statement, the results are unpredictable. (A transfer is made to the absolute memory address represented by the low order 18 bits of `iv`.)

The ASSIGN statement assigns to the variable one of the statement labels specified in parentheses.

Example:

```
GO TO NAPA,(5,15,25)
```

If 5 is assigned to NAPA, statement 5 is executed next. If 15 is assigned to NAPA, statement 15 is executed next. If 25 is assigned to NAPA, statement 25 is executed next.
ARITHMETIC IF

THREE BRANCH

expression < 0 branch to sn1
expression = 0 branch to sn2
expression > 0 branch to sn3

This statement transfers control to sn1 if the value of the arithmetic or masking expression is less than zero, sn2 if it is equal to zero, or sn3 if it is greater than zero. Zero is defined as a word containing all bits set to zero or all bits set one (+0 or -0).

Example:

```
PROGRAM IF (INPUT,OUTPUT,TAPE5=INPUT,TAPE6=OUTPUT)
  READ (5,100) I,J,K,N
100 FORMAT (10X,4I4)
  IF(I-N) 3,4,6
  3 ISUM=J+K
  6 CALL ERROR1
     PRINT 2, ISUM
  2 FORMAT (I10)
  4 STOP
END
```

If the type of the evaluated expression is complex, only the real part is tested.

ARITHMETIC IF

TWO BRANCH

expression is a masking or arithmetic expression

This statement transfers control to sn3 if the value of the expression is not equal to 0, and to sn2 if it is equal to 0.
Example:

```
    IF (I*J*DATA(K))100,101
100 IF (I*Y*K)105,106
```

**LOGICAL IF**

```
    IF (logical or relational expression) stat
```

stat is any executable statement other than DO, END or a logical IF.

If the expression is true, stat is executed. If the expression is false, the statement immediately following the IF statement is executed.

```
    .FALSE. = +0
    .TRUE.  is any value other than +0
```

Examples:

```
    IF (P.AND.Q) RES=7.2
    50 TEMP=ANS+Z
```

If P and Q are both true, the value of the variable RES is replaced by 7.2. Otherwise, the value of RES is unchanged. In either case, statement 50 is executed.

```
    IF (A.LE. 2.5) CASH=150.
    70 B=A+C-TEMP
```

If A is less than or equal to 2.5, the value of CASH is replaced by 150. If A is greater than 2.5 CASH remains unchanged.

```
    IF (A.LT.B) CALL SUB1
    20 ZETA=TEMP+RES4
```

If A is less than B, the subroutine SUB1 is called. Upon return from this subroutine, statement 20 is executed. If A is greater than or equal to B, statement 20 is executed, and SUB1 is not called.
LOGICAL IF

TWO BRANCH

IF (logical or relational expression) sn₁,sn₂

If the value of the expression is true, sn₁ is executed. If the value of the expression is false, sn₂ is executed.

Example:

IF(K.EQ.100)60,70

If K is equal to 100, statement 60 is executed; otherwise statement 70 is executed.

DO STATEMENT

DO sn iv=m₁,m₂,m₃

iv is a non-subscripted integer variable called the index

m₁, m₂, m₃, the indexing parameters, may be unsigned integer or octal constants or simple integer variables with positive values no larger than \(2^{17}-2\). If m₁ is not specified, it is assigned the value 1. If the indexing parameters exceed \(2^{17}-2\) (or 10 digits) with or without leading zeros, the performance of the loop is unspecified.

The DO statement is used to execute repeatedly a section of program up to and including the statement labeled sn. sn must be an executable statement in the same program unit as the DO statement. If m₁ exceeds m₂ on initial entry to the loop, the loop is executed once; and control passes to the statement following sn.

m₁ is the initial value assigned to iv; m₂ is the limit value, and m₃ is the amount added to the initial value each time the DO loop is executed. When the value of iv exceeds m₂, the DO loop is completed; and control passes to the statement following sn. At execution, m₁, m₂, and m₃ must be greater than zero. The range of each DO loop contains all executable statements between and including the first executable statement after the DO and the terminal statement identified by sn. An extended range is a transfer of control out of the range of a DO loop followed by a transfer back into the same DO loop.

The control variable and the parameters m₁, m₂, and m₃ may not be redefined during execution of the immediate or extended range of the DO. When parameters are redefined during execution, the results are unpredictable. An informative diagnostic is issued for redefinition during an immediate range.
The last statement in a DO loop must not be an arithmetic IF or GO TO statement, a two branch logical IF, a RETURN, END, STOP, PAUSE or another DO statement, or a logical IF containing any of the preceding statements.

Examples:

```
DO 10 I=1,11,3
   IF(ALIST(I)-ALIST(I+1))15,10,10
   15 ITMP=ALIST(I)
   10 ALIST(I)=ALIST(I+1)
300 WRITE(6,200)ALIST
```

The statements following DO up to and including statement 10 are executed 4 times. The DO loop is executed with I equal to 1,4,7,10. Statement 300 is then executed.

```
K=3
J=5
DO 100 I=J,K
   RACK=2.-3.5+ANT(I)
100 CONTINUE
```

The DO loop would be executed once only (with I=5) because J is larger than K.

```
DO 10 I=1,5
   CAT=BOX+D
   10 IF (X.GT.B.AND.X.LT.H)Z=EQUATE
       6 A=ZERO=EXTRA
```

Statement 10 is executed five times whether or not Z = EQUATE is executed. Statement 6 is executed only after the DO loop is satisfied.

After the last execution of the DO loop, control passes to the statement following sn, and the DO is satisfied. When the DO is satisfied, the index variable iv becomes undefined. A transfer out of the range of a DO loop is permissible at any time. When such a transfer occurs, the index variable iv remains defined as its most recent value in the loop.

Example:

```
IVAR = 9
   .
   .
   DO 20 I = 1,200
      IF (I-IVAR) 20,10,10
20 CONTINUE
10 IN = I
```

An exit from the range of the DO is made to statement 10 when the value of the control variable I is equal to IVAR. The value of the integer variable, IN, becomes 9.
LOOP TRANSFER

The range of a DO statement may include other DO statements providing the range of each inner DO is entirely within the range of the containing DO statement. The last statement of an inner DO loop must be either the same as the last statement of the outer DO loop or occur before it.

If more than one DO loop has the same terminal statement, a transfer to that statement may be made only from within the range (or extended range) of the innermost DO. When a DO loop contains another DO loop, the grouping is called a DO nest. DO loops may be nested to 50 levels.

Example:

```
DIMENSION A(5,4,4), B(4,4)
DO 2 I = 1,4
DO 2 J = 1,4
DO 1 K = 1,5
1 A(K,J,I) = 0.0
2 B(J,I) = 0.0
```

Examples:

DO loops may be nested in common with other DO loops:

```
D1
   D2
      D3
      n3
      n2
   D4
      n2
      n4

D1
   D2
      D3
      n3
      n2

D1
   D2
      D3
      n3
      n1 = n2 = n3
```
The preceding diagrams could be coded as follows:

```
DO 1 I=1,10,2
   .
   .
DO 2 J=1,5
   .
   .
   .
DO 3 K=2,8
  10 CONTINUE
   .
   .
3 CONTINUE
   .
   .
   .
2 CONTINUE
   .
   .
   .
20 CONTINUE
   .
   .
   .
DO 4 L=1,3
  100 CONTINUE
   .
4 CONTINUE
   .
1 CONTINUE
```

A DO loop may be entered only through the DO statement. Once the DO statement has been executed, and before the loop is satisfied, control may be transferred out of the range and then transferred back into the range of the DO.

A transfer from the range of an outer DO into the range of an inner DO loop is not allowed. However, a transfer out of the range of an inner DO into the range of an outer DO is allowed because such a transfer is within the range of the outer DO loop.
The use of, and return from, a subprogram within a DO loop is permitted. A transfer back into the range of an innermost DO loop is allowed if a transfer has been made from that same loop.

![Legal Diagram](image1)

![Illegal Diagram](image2)

When a statement is the terminal statement of more than one DO loop, the label of that terminal statement may not be used in any GO TO or IF statement in the nest, except in the range of the innermost DO.

Example:
```
DO 10 J=1,50
  DO 10 I=1,50
  DO 10 M=1,100
  
  G0 TO 10
  
  10 CONTINUE
```

When the IF statement is used to bypass several inner loops, different terminal statements for each loop are required.
Example:

DO 10 K=1,100
   IF(DATA(K)-10.)20,10,20
20  DO 30 L=1,20
   IF(DATA(L)-FACT*K-10.)40,30,40
40  DO 50 J=1,5
   .
   .
   .
   GO TO (101,102,50),INDEX
101  TEST=TEST+1
   GO TO 104
103  TEST=TEST-1
   DATA(K)=DATA(K)*2.0
   .
   .
   .
50  CONTINUE
30  CONTINUE
10  CONTINUE
   .
   .
   .
   GO TO 104
102  DO 109 M=1,3
   .
   .
   .
109  CONTINUE
   GO TO 103
104  CONTINUE

In the following illustration, transfers 2, 3, and 4 are acceptable; 1, 5, and 6 are not.
CONTINUE

Example:

```plaintext
DO 10 I = 1,11
  IF (A(I)-A(I+1))20,10,10
20 ITEMPP = A(I)
  A(I) = A(I-1)
10 CONTINUE
```

CONTINUE is a statement that may be placed anywhere in the source program without affecting the sequence of execution. It is used most frequently as the last statement in the range of a DO loop to avoid ending the loop with an illegal statement. The CONTINUE statement should contain a statement label in columns 1-5. If it does not, it serves no purpose; and an informative diagnostic is provided.

```
DO 20 I=1,20
  1 IF (X(I) - Y(I))20,20,20
    X(I) = X(I)+1.0
    Y(I) = Y(I)-2.0
    GO TO 1
20 CONTINUE
```

The use of the CONTINUE statement avoids ending the DO loop with the statement GO TO 1.

PAUSE

```
PAUSE

PAUSE n

PAUSE # c...c #
```

n is a string of 1-5 octal digits.

c...c is a string of 1-70 characters.

When a PAUSE statement is encountered during execution, the program halts and PAUSE n, or c...c. appears as a dayfile message on the display console. The operator can continue or terminate the program with an entry from the console. The program continues with the next statement. If n is omitted, blanks are implied.
STOP

n is a string of 1-5 octal digits.

c...c is a string of 1-70 characters.

When a STOP statement is encountered during execution, STOP n, or STOP c...c, is displayed in the dayfile, the program terminates and control returns to the operating system. If n is omitted, blanks are implied. A program unit may contain more than one STOP statement.

END

The END line terminates compilation of a program unit. This line should be the last statement in a program or subprogram. If an END line is omitted and a SCOPE end of record or end of file immediately follows the last source program statement, an informative diagnostic is printed.

If an END statement is executed in a subprogram, control returns to the calling program. When an END statement is encountered in the main program of an overlay, control returns to the statement following the CALL OVERLAY statement which initialized loading and execution of the overlay.

The END line can follow a statement separator (S), and can be continued. No blank cards, nor blank continuation cards, should follow the card containing the final character D. If they do, an informative diagnostic is printed.
PROGRAM RLIST (INPUT, OUTPUT)
READ 5,X,Y,Z
5 FORMAT (3F10.4)
RESULT = X-Y+Z
PRINT 100, RESULT
100 FORMAT (11H1 RESULT IS ,F7.3)
END

RETURN

RETURN i

i is a dummy argument which appears in the RETURNS list

RETURN returns control from a subprogram to the calling program. Control returns to the next executable statement following the CALL. In function subprograms, a RETURN statement returns control to the statement containing the function reference. A subprogram may contain more than one RETURN statement. A RETURN statement in a main program has the same effect as an END line, and an informative message is issued during compilation.

Example:

A = SUBFUN (D,E)    FUNCTION SUBFUN(X,Y)
10 DO 200 I = 1,5
   SUBFUN = X/Y
   RETURN
   END

RETURN i can appear only in a SUBROUTINE subprogram with a RETURNS list. (A RETURN i in a FUNCTION subprogram causes a fatal error at compilation time.) The statement labels in the RETURNS list in the CALL statement correspond to the dummy statement labels in the SUBROUTINE statement in the SUBROUTINE subprogram. When a SUBROUTINE subprogram is called, the actual statement labels replace the dummy statement labels. Execution of RETURN i returns control to the statement label corresponding to i in the RETURNS list.
Example:

    PROGRAM MAIN (INPUT,OUTPUT)
    .
    .
    10  CALL XCOMP(A,B,C),RETURNS(101,102,103,104)
    .
    .
    101  CONTINUE
    .
    .
    GO TO 10
    102  CONTINUE
    .
    .
    GO TO 10
    103  CONTINUE
    .
    .
    GO TO 10
    104  CONTINUE
    END

    SUBROUTINE XCOMP (B1,B2,C),RETURNS(A1,A2,A3,A4)
    IF(B1*B2-4.159)10,20,30
    10  CONTINUE
    .
    .
    RETURN A1
    20  CONTINUE
    .
    .
    RETURN A2
    30  CONTINUE
    .
    .
    .
    IF (B1)40,50
    40  RETURN A3
    50  RETURN A4
    END

Program MAIN passes statement labels 101, 102, 103 and 104 to subroutine XCOMP to replace the dummy RETURNS arguments A1, A2, A3 and A4. If RETURN A1 is reached in the subroutine, a return is made to statement 101; if A2 is reached, a return is made to statement 102. A3 to 103, and A4 to 104.
Example:

```
SUBROUTINE XYZ(P,I,U),RETURNS(A,B,C)
IF (P .T. U) 1,2,3
1 CONTINUE
2 CONTINUE
3 RETURN C
END
```

Example:

```
FUNCTION Y(X)
IF (X.LT. 3.2) GO TO 30
40 Y = 0.7 * X + 1.237
RETURN
30 Y = 0.012 * X + 7.2
RETURN
END
```
Specification statements are non-executable; they define the type of a variable or array, specify the amount of storage allocated to each variable according to its type, specify the dimensions of arrays, define methods of sharing storage, and assign initial values to variables.

**IMPLICIT**

The IMPLICIT statement must precede other specification statements

**Type**

**DIMENSION**

If any of these statements appear after the first executable statement or statement function definition, it is ignored and a fatal diagnostic is printed.

**COMMON**

**EQUIVALENCE**

**EXTERNAL**

**LEVEL**

The DATA statement should precede the first executable statement. If a DATA statement appears after the first executable statement, it must not define variables or arrays referenced in the preceding executable statements.

**DATA**

**TYPE STATEMENTS**

A type statement explicitly defines a variable, array, or function to be integer, real, complex, double precision, or logical. The type statement may be used to supply dimension information. The word TYPE as a prefix is optional.

A symbolic name not explicitly defined in a type, FUNCTION or IMPLICIT statement is implicitly defined as type integer if the first letter of the name is I,J,K,L,M,N; if it is any other letter, the type is real. An explicit definition can override or confirm an implicit definition.

Basic external and intrinsic functions are implicitly typed, and need not appear in a type statement in the user’s program. The type of each library function is listed in section 8.
EXPLICIT DECLARATIONS

INTEGER

\[
\text{INTEGER } \text{name}_1, \text{name}_2, \ldots, \text{name}_n
\]

The symbolic names listed are declared to be of type integer.

Example:

\[
\text{INTEGER } \text{SUM, RESULT, ALIST}
\]

The variables SUM, RESULT and ALIST are all defined as type integer.

REAL

\[
\text{REAL } \text{name}_1, \text{name}_2, \ldots, \text{name}_n
\]

Example:

\[
\text{REAL } \text{LIST, JOB3, MASTER4}
\]

The variables LIST, JOB3, and MASTER4 are all defined as type real.

A real variable is stored in floating point format in one word in memory.

COMPLEX

\[
\text{COMPLEX } \text{name}_1, \text{name}_2, \ldots, \text{name}_n
\]

The symbolic names listed are defined as type complex.

Example:

\[
\text{COMPLEX } \text{ALPHA, NAM, MASTER, BETA}
\]

The variables ALPHA, NAM, MASTER, BETA are defined as type complex.

A complex variable is stored as two floating point numbers in two consecutive 60-bit words in memory; the first word is the real part, and the second word is the imaginary part.
DOUBLE PRECISION

7

DOUBLE PRECISION name_1, name_2, ..., name_n

Double precision variables occupy two consecutive words of memory; the first for the most significant part and the second for the least significant part.

The symbolic names listed are declared to be of type double precision. DOUBLE may be used instead of DOUBLE PRECISION.

Example:

DOUBLE PRECISION ALIST, JUNR, BOX4

The variables ALIST, JUNR, BOX4 are defined as type double precision.

LOGICAL

7

LOGICAL name_1, name_2, ..., name_n

The symbolic names listed are defined as type logical.

Example:

LOGICAL P, Q, NUMBR4

The variables P, Q and NUMBR4 are defined as type logical.

IMPLICIT STATEMENT

7

IMPLICIT type_1(ac_1, ..., ac_n), ..., type_n(ac_1, ..., ac_n)

<table>
<thead>
<tr>
<th>type</th>
<th>LOGICAL, INTEGER, REAL, DOUBLE PRECISION, or COMPLEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>(ac)</td>
<td>Single alphabetic character, or range of characters represented by the first and last character separated by a minus sign. ac must be enclosed in parentheses.</td>
</tr>
</tbody>
</table>

Example:

IMPLICIT REAL (I-M, X), COMPLEX (A-D, N)
This statement specifies the type of variables or array elements beginning with the letters ac. Only one IMPLICIT statement may appear in a program unit, and it must precede other specification statements. An IMPLICIT statement in a FUNCTION or SUBROUTINE subprogram affects the type of dummy arguments and the function name, as well as other variables in the subprogram.

Explicit typing of a variable name or array element in a type statement or FUNCTION statement overrides an IMPLICIT specification.

Examples:

```
IMPLICIT INTEGER(A-D,N,R)
DIMENSION GRAD (10,2)
ASUM = BOR + ROR * ANEXT
DECK = CROWN + B
```

The variables ASUM, BOR, ROR, ANEXT, DECK, CROWN and B are of type integer.

In the following example the statement INTEGER A,B,C,D can be replaced by an IMPLICIT statement

```
PROGRAM COME (OUTPUT,TAPE6=OUTPUT)
COMMON A(10),B,C,D
INTEGER A,B,C,D

PROGRAM COME (OUTPUT,TAPE6=OUTPUT)
IMPLICIT INTEGER (A-D)
COMMON A(10),B,C,D
```

Example:

The statement INTEGER A,B,C,D,E(3,4),F,H is replaced by an IMPLICIT statement. A DIMENSION statement is added since an IMPLICIT statement cannot be used to dimension an array. The IMPLICIT statement must also precede all other specification statements.

```
PROGRAM COME (OUTPUT,TAPE6=OUTPUT)
COMMON A(1),B,C,D, F,G,H
INTEGER A,B,C,D,E(3,4),F,H
EQUIVALENCE (A,E,I)
NAMELIST/VLIST/A,B,C,D,E,F,G,H,I

DO 1 J = 1, 12
1   A(J)=J

WRITE (6,VLIST)
STOP
END
```
PROGRAM COME (OUTPUT, TAPE6=OUTPUT)
IMPLICIT INTEGER (A-F,H)
DIMENSION E(3,4)
COMMON A(1), B, C, D, F, G, H
EQUIVALENCE (A, E, I)
NAMELIST/VLIST/A, B, C, D, E, F, G, H, I

DO 1 J = 1, 12
  1 A(J) = J

WRITE (6, VLIST)
STOP
END

STORAGE ALLOCATION

SUBSCRIPTS

A subscripted symbolic name in the type specification is the name of an array, and the product of the subscripts is the number of elements in the array.

Example:

INTEGER ZERO(3,3)

defines ZERO as an array of type integer containing 9 integer elements.

REAL NEXT(7), ITEM

defines NEXT as an array with 7 real elements, and ITEM as a real variable

INTEGER CANS(10), NRUMS(7,3), BOX

defines CANS as an integer array with 10 elements, NRUMS as an integer array with 21 elements, and BOX as an integer variable
Dimension information should be specified only once for any array name, a second specification is ignored but a warning message is printed.

Examples:

```
INTEGER ZERO(3,3)   \{ invalid if both statements appear in the same program; second
DIMENSION ZERO(4,3) \{ definition is ignored

INTEGER CAT
DIMENSION CAT(4,3,2)
```

These statements could be shortened to one statement:

```
INTEGER CAT(4,3,2)
```

**DIMENSION STATEMENT**

```
7
```

Discuss the diagram of the `DIMENSION` statement.

- `d_i`: Array declarator, 1-3 integer constants. In a subprogram `DIMENSION` statement, they can be integer variables.
- `name_1,...,name_n`: Symbolic name of an array

```plaintext
PROGRAM SUM (INPUT,OUTPUT,TAPES=INPUT,TAPE6=OUTPUT)
  DIMENSION INK (10)
  READ (5,100) INK
  100 FORMAT (10I4)
  DO 4 I = 1,10
    4  ITOT = ITOT + INK(I)
  WRITE (6,200) ITOT
  200 FORMAT (10X,*TOTAL = *, I4)
END
```

`DIMENSION` is a non-executable statement which defines symbolic names as array names and specifies the bounds of the array.

Example:

```
DIMENSION TOTAL (7,2)
```

TOTAL is defined as a real array of 14 elements.

More than one array can be declared in a single `DIMENSION` statement.

Example:

```
DIMENSION A(10),B(7,5),C(20,2,4)
```

The number of computer words reserved for an array is determined by the product of the subscripts and the type of the array. For real, integer and logical arrays, the number of words in an array equals the number of elements in the array. For complex and double precision arrays, the number of words reserved is twice the product of the subscripts.
Example:

```
COMPLEX BETA
DIMENSION BETA (2,3)
```

BETA is an array containing six elements; however, BETA has been defined as COMPLEX and two words are used to contain each complex element; therefore, 12 computer words are reserved.

```
REAL NIL
DIMENSION NIL (8,2,2) reserves 24 words for the array NIL
```

Example:

```
DIMENSION ASUM(10,2)
.
.
.
DIMENSION ASUM (3), VECTOR (7,7)
```

The second specification of ASUM is ignored, and an informative message is printed. The specification for VECTOR is valid and is processed.

**ADJUSTABLE DIMENSIONS**

Within a subprogram, array dimension specifications may use integer variables, as well as integer constants, provided the array name and all the variable names used for array dimension specifications are dummy arguments of the subprogram. The actual array name and values for the dummy variables are defined by the calling program.

```
FUNCTION DTOTAL (ARRAY,N)
DIMENSION ARRAY (N,N)
DTOTAL = 0.
DO 1 I = 1,N
  1 DTOTAL = DTOTAL + ARRAY (I,I)
RETURN
END
```

The above function totals the elements on the major diagonal of any square array. The array name and dimensions are arguments.

A further explanation of adjustable dimensions appears in section 7.
COMMON

COMMON / \(v_1, \ldots, v_n\)

COMMON/blkname\(/v_1, \ldots, v_n\)/blkname\(/v_1, \ldots, v_n\)

7

COMMON \(v_1, \ldots, v_n\)

blkname

Block name or number enclosed in slashes. A block name is a symbolic name. A block number is 1-7 digits; it must not contain any alphabetic characters. Leading zeros are ignored. 0 is a valid block number. The same block name or number can appear more than once in a COMMON statement or a program unit; the SCOPE loader links all variables in blocks having the same name or number into a single labeled common block.

\(v_1, \ldots, v_n\)

Variables or array names which can be followed by constant subscripts that declare the dimensions. The variable or array names are assigned to blkname. The COMMON statement can contain one or more block specifications.

//

Denotes a blank common block. If blank common is the first block in the statement, slashes can be omitted.

Example:

```fortran
PROGRAM CMN (INPUT, OUTPUT)
  COMMON NED (10)
  READ 3+NED
  3 FORMAT (10I3)
  CALL JAVG
  STOP
END
```

Variables or arrays in a calling program or a subprogram can share the same storage locations with variables or arrays in other subprograms by means of the COMMON statement. Variables and array names are stored in the order in which they appear in the block specification.

COMMON is a non-executable statement. If DIMENSION, COMMON and type specifications appear together, the order is immaterial. The COMMON specification provides up to 125 storage blocks that can be referenced by more than one subprogram. A block of common storage can be labeled by a name or a number. A COMMON statement without a name or number refers to a blank common block. Variables and array elements can appear in both COMMON and EQUIVALENCE statements. A common block of storage can be extended by an EQUIVALENCE statement.
All members of a common block must be allocated to the same level of storage; a fatal diagnostic is issued if conflicting levels are declared. An informative diagnostic is issued if some, but not all, members of a common block are declared in LEVEL statements, and all members are assigned to the declared level.

If any common block member is extended core storage (ECS) resident (section 6, part 3) all members of the block must be ECS resident. No ECS resident elements can appear in blank common.

Block names can be used elsewhere in the program as symbolic names, and they can be used as subprogram names. Numbered common is treated as labeled common. Data stored in common blocks by the DATA statement is available to any subprogram using these blocks.

The length of a common block, other than blank common, must not be increased by a subprogram using the block unless the subprogram is loaded first by the SCOPE loader.

Example:

```
COMMON/BLACK/A(3)
DATA A/1,2,3/,

COMMON/100/I(4)
DATA I/4,5,6,7/
```

Data may not be entered into blank common blocks by the DATA declaration.

The COMMON statement may contain one or more block specifications:

```
COMMON/X/RAG,TAG/APPA/Y,Z,B(5)
```

RAG and TAG are placed in block X. The array B and Y,Z are placed in block APPA.

Any number of blank common specifications can appear in a program. Blank, named and numbered common blocks are cumulative throughout a program, as illustrated by the following example:

```
COMMON A,B,C/X/Y,Z,D//W,R
.
.
COMMON M,N/CAT/ALPHA,BINGO//ADD
```

Have the same effect as the single statement:

```
```

Within subprograms, dummy arguments are not allowed in the COMMON statement.

If dimension information for an array is not given in the COMMON statement, it must be declared in a type or DIMENSION statement in that program unit.
Examples:

```
COMMON/DEE/Z(10,4)
```

Specifies the dimensions of the array Z and enters Z into labeled common block DEE.

```
COMMON/BLOKE/ANARAY,B,D
DIMENSION ANARAY(10,2)

COMMON/Z/X,Y,A
REAL X(7)

COMMON/HAT/M,N,J(3,4)
DIMENSION J(2,7)
```

In the last example, J is defined as an array (3,4) in the COMMON statement. (2,7) in the DIMENSION statement is ignored and an error message is printed.

The length of a common block, in computer words, is determined by the number and type of the variables and array elements in that block. In the following statements, the length of common block A is 12 computer words. The origin of the common block is Q(1).

```
REAL Q,R
COMPLEX S
COMMON/A/Q(4),R(4),S(2)
```

<table>
<thead>
<tr>
<th>Block A</th>
<th>origin</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Q(1)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Q(2)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Q(3)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Q(4)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R(1)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R(2)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R(3)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>R(4)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>S(1)</td>
<td>real part</td>
</tr>
<tr>
<td></td>
<td>S(1)</td>
<td>imaginary part</td>
</tr>
<tr>
<td></td>
<td>S(2)</td>
<td>real part</td>
</tr>
<tr>
<td></td>
<td>S(2)</td>
<td>imaginary part</td>
</tr>
</tbody>
</table>

If a program unit does not use all locations reserved in a common block, unused variables can be inserted in the COMMON declaration in the subprogram to ensure proper correspondence of common areas.
Example:

```plaintext
COMMON/SUM/A,B,C,D main program
COMMON/SUM/E(3),D subprogram
```

If the subprogram does not use variables A, B, and C, array E is necessary to space over the area reserved by A, B, and C.

Alternatively, correspondence can be ensured by placing unused variables at the end of the common list.

```plaintext
COMMON/SUM/D,A,B,C main program
COMMON/SUM/D subprogram
```

If program units share the same common block, they may assign different names and types to the members of the block; but the block name or numbers must remain the same.

Example:

```plaintext
PROGRAM MAIN
COMPLEX C
COMMON/TEST/C(20)/36/A,B,Z
```

The block named TEST consists of 40 computer words. The length of the block numbered 36 is three computer words.

The subprogram may use different names as in:

```plaintext
SUBROUTINE ONE
COMPLEX A
COMMON/TEST/A(10),G(10),K(10)
```

The length of TEST is 40 words. The first 10 elements (20 words) of the block represented by A are complex elements. Array G is the next 10 words, and array K is the last 10 words. Within the subprogram, elements of G are treated as floating point; elements of K are treated as integer.

**EQUIVALENCE STATEMENT**

![EQUIVALENCE Diagram](image)

\[ v_1, \ldots, v_n \text{ are variables, array elements, or array names which can be of different types.} \]

Subscripts must be integer constants. The parentheses are part of the EQUIVALENCE group and must be present. Two or more variables, array elements, or array names can be included in an equivalence group. Dummy arguments and constants are not allowed. More than one equivalence group can appear. ECS resident variables or array elements are not allowed in an equivalence group. Equivalented variables must be assigned to the same level of storage.
Example:

```
PROGRAM EQUIV (OUTPUT, TAPE6=OUTPUT)
EQUIVALENCE (X,Y), (Z,I)
NAMELIST/OUTPUT/X,Y,Z,I
X=1.
Y=2.
Z=3.
I=4
WRITE (6, OUTPUT)
STOP
END

$OUTPUT
X = 0.2E+01,
Y = 0.2E+01,
Z = 0.0,
I = 4,
$END
```

An explanation of this example appears in part 2.
EQUIVALENCE is a non-executable statement and must appear before all executable statements in a program unit. If it appears after the first executable statement, a fatal diagnostic is printed. Variables or array elements not mentioned in an EQUIVALENCE statement are assigned unique locations.

EQUIVALENCE assigns two or more variables in the same program unit to the same storage location (as opposed to COMMON which assigns two variables in different program units to the same location).

Example:

```
DIMENSION JAN(6), BILL(10)
EQUIVALENCE (IRON, MAT, ZERO), (JAN(5), BILL(2)), (A, B, C)
```

The variables IRON, MAT and ZERO share the same location, the fifth element in array JAN and the second element in array BILL share the same location, and the variables A, B and C share the same location.

When an element of an array is referred to in an EQUIVALENCE statement, the relative locations of the other array elements are, thereby, defined also.

Example:

```
DIMENSION Y(4), B(3,2)
EQUIVALENCE (Y, B(1,2)), (X, Y(4))
```

This EQUIVALENCE statement causes storage to be shared by the first element in Y and the fourth element in B and, similarly, the variable X and the fourth element in Y. Storage will be as follows:

```
 B(1,1)
 B(2,1)
 B(3,1)
 B(1,2) Y(1)
 B(2,2) Y(2)
 B(3,2) Y(3)
     Y(4)   X
```

The statement EQUIVALENCE(A,B),(B,C) means the same as EQUIVALENCE (A,B,C).

When no array subscript is given, it is assumed to be 1.

```
DIMENSION ZEBRA(10)
EQUIVALENCE (ZEBRA, TIGER)
```

Means the same as the statements:

```
DIMENSION ZEBRA(10)
EQUIVALENCE (ZEBRA(1), TIGER)
```

A logical, integer, or real entity equivalenced to a double precision or complex entity shares the same location as the real or most significant part of the complex or double precision entity.
An array with multiple dimensions may be referenced with a single subscript. The location of the element in the array may be determined by the following method:

\[
\text{DIMENSION } A(K,M,N)
\]

The position of element \( A(k,m,n) \) is given by:

\[
A+(k-1+K^*(m-1+M^*(n-1)))*E
\]

E is 1 if \( A \) is real, integer or logical; E is 2 if \( A \) is complex or double precision.

Example:

\[
\text{DIMENSION AVERAG(2,3,4),TERM(7)}
\]
\[
\text{EQUIVALENCE (AVERAG(8),TERM(2))}
\]

Elements AVERAG(2,1,2) and TERM(2) share the same locations.

Two or more arrays can share the same storage locations.

Example:

\[
\text{DIMENSION ITIN(10,10),TAX(100)}
\]
\[
\text{EQUIVALENCE(ITIN,TAX)}
\]

\[
\text{.}
\]

\[
\text{.}
\]

\[
500 \text{ READ (5,40) ITIN}
\]

\[
\text{.}
\]

\[
\text{.}
\]

\[
600 \text{ READ (5,70) TAX}
\]

The EQUIVALENCE declaration assigns the first elements of arrays TIN and TAX to the same location. READ statement 500 stores the array TIN in consecutive locations. Before READ statement 600 is executed, all operations involving ITIN should be completed; as the values of array TAX are read into the storage locations previously occupied by ITIN.

Lengths of arrays need not be equal.

Examples:

\[
\text{DIMENSION ZERO1(10,5),ZERO2(3,3)}
\]
\[
\text{EQUIVALENCE (ZERO1,ZERO2)} \quad \text{is a legal EQUIVALENCE statement}
\]

\[
\text{EQUIVALENCE (ITEM,TEMP)}
\]

The integer variable ITEM and the real variable TEMP share the same location; therefore, the same location may be referred to as either integer or real. However, the integer and real internal formats differ; therefore the values will not be the same.
Example:

```
PROGRAM COME (OUTPUT, TAPE6=OUTPUT)
COMMON A(1), B, C, D, F, G, H
INTEGER A, B, C, D, E(3,4), F, H
EQUIVALENCE (A, E, I)
NAMELIST/VLIST/A, B, C, D, E, F, G, H, I

DO 1 J = 1, 12
  1  A(J) = J

WRITE (6, VLIST)
STOP
END
```

Output from Program COME:

```
$VLIST
A    = 1,
B    = 2,
C    = 3,
D    = 4,
E    = 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12,
F    = 5,
G    = 0.0,
H    = 7,
I    = 1,
$END
```

An explanation of this example appears in part 2.
EQUIVALENCE AND COMMON

Variables, array elements, and arrays may appear in both COMMON and EQUIVALENCE statements. A common block of storage may be extended by an EQUIVALENCE statement.

Example:

    COMMON/HAT/A(4),C
    DIMENSION B(5)
    EQUIVALENCE (A(2),B(1))

Common block HAT will extend from A(1) to B(5):

/HAT/

<table>
<thead>
<tr>
<th>Origin</th>
<th>A(1)</th>
<th>B(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A(2)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A(3)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A(4)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>B(4)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>B(5)</td>
<td></td>
</tr>
</tbody>
</table>

EQUIVALENCE statements which extend the origin of a common block are not allowed, however.

Example:

    COMMON/DESK/E,F,G
    DIMENSION H(4)
    EQUIVALENCE (E,H(3))

The above EQUIVALENCE statement is illegal because H(1) and H(2) extend the start of the common block DESK:

/DESK/

<table>
<thead>
<tr>
<th>origin</th>
<th>E</th>
<th>H(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td></td>
<td>H(4)</td>
</tr>
<tr>
<td>G</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

No two elements in the same common block or in different common blocks may be set equivalent to each other.
Examples:

```
COMMON A, B, C
EQUVALENCE (A, B)    illegal

COMMON /HAT/ A(4), C /X/ Y, Z
EQUVALENCE (C, Y)    illegal
```

**LEVEL STATEMENT**

```
  7
  LEVEL n, a1, ..., an
```

- \(a_1, ..., a_n\): List of variables or array names separated by commas
- \(n\): Unsigned integer 1, 2, or 3 indicating level to which list is to be allocated.
  - 1: Small core memory resident (SCM)
  - 2: Large core memory resident (LCM). Directly addressable (or word addressable)
  - 3: Large core memory resident, accessed by block transfer to or from small core memory through MOVLEV subroutine call
  - 1: Central memory resident
  - 2: Central memory resident
  - 3: Extended core storage resident, accessed by block transfer to or from central memory through MOVLEV subroutine call

This statement assigns variables or array names to the level \(n\). LEVEL statements must precede the first executable statement in a program unit. Names of variables and arrays which do not appear in a LEVEL statement are allocated to small core memory (level 1) in 7600, and central memory (levels 1 and 2) in 6000 series computers.

No dimension or type information may be included in the LEVEL statement.

Variables and arrays appearing in a LEVEL statement can appear in DATA, DIMENSION, EQUIVALENCE, COMMON, type, SUBROUTINE and FUNCTION statements. Data assigned to levels 2 and 3 must appear also in COMMON statements or as dummy arguments in SUBROUTINE statements.
Data assigned to level 3 can be referenced only in COMMON, CALL, SUBROUTINE, FUNCTION and DIMENSION statements. Level 3 items cannot be used in expressions.

No restrictions are imposed on the way in which reference is made to variables or arrays allocated to levels 1 and 2.

If the level of any variable is multiply defined, the level first declared is assumed; and a warning diagnostic is printed.

All members of a common block must be assigned to the same level; a fatal diagnostic is issued if conflicting levels are declared. If some, but not all, members of a common block are declared in a LEVEL statement, all are assigned to the declared level, and an informative diagnostic is printed.

If a variable or array name declared in a LEVEL statement appears as an actual argument in a CALL statement, the corresponding dummy argument must be allocated to the same level in the called subprogram.

If a variable or array name appears in an EQUIVALENCE and a LEVEL statement, the equivalenced variables must all be allocated to the same level.

Example:

```
DIMENSION E(500), B(500), CM(1000)
LEVEL 3, E, B
COMMON /ECSBLK/ E, B
.
.
CALL MOVLEV (CM, E, 1000)
```

The LEVEL statement allocates arrays E and B to extended core storage or to LCM. They are assigned to a named common block, ECSBLK. Starting at location CM (the first word address of the array CM), 1000 words of central memory are transferred to the two arrays E and B in extended core storage or LCM by the library routine MOVLEV.

**EXTERNAL STATEMENT**

```
7
<table>

</table>
```

name_1,...,name_n

Subprogram names

Before a subprogram name is used as an argument to another subprogram, it must be declared in an EXTERNAL statement in the calling program.
Any name used as an actual argument in a call is assumed to be a variable or array unless it appears in an EXTERNAL statement. An EXTERNAL statement must be used even if the subprogram concerned is a standard system function, such as SQRT. However, an EXTERNAL statement is not required for intrinsic functions used as actual arguments. If an intrinsic function name appears in an EXTERNAL statement, the user must supply the function.

Example:

<table>
<thead>
<tr>
<th>Calling Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL SIN, SQRT</td>
<td>SUBROUTINE SUBRT (A,B,C)</td>
</tr>
<tr>
<td>CALL SUBRT(2.0,SIN,RESULT)</td>
<td>X=A+3.14159/2.</td>
</tr>
<tr>
<td>WRITE (6,100) RESULT</td>
<td>C=B(X)</td>
</tr>
<tr>
<td>100 FORMAT (F7.3)</td>
<td>RETURN</td>
</tr>
<tr>
<td>CALL SUBRT(2.0,SQRT,RESULT)</td>
<td>END</td>
</tr>
<tr>
<td>WRITE (6,100)RESULT</td>
<td></td>
</tr>
<tr>
<td>STOP</td>
<td></td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
</tbody>
</table>

First the sine, then the square root are computed; and in each case, the value is returned in RESULT. The EXTERNAL statement must precede the first executable statement, and always appears in the calling program. (It may not be used with statement functions.)

A function call that provides values for an actual argument does not need an EXTERNAL statement.

Example:

<table>
<thead>
<tr>
<th>Calling Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL SUBRT(SIN(X),RESULT)</td>
<td>SUBROUTINE SUBRT(A,B)</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>B=A</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
</tbody>
</table>

An EXTERNAL statement is not required because the function SIN is not the argument of the subprogram; the evaluated result of SIN(X) becomes the argument.
Example:

PROGRAM VARDIM2(OUTPUT,TAPE6=OUTPUT,DEBUG=OUTPUT)
COMMON X(4,3)
REAL Y(6)
EXTERNAL MULT, AVG
NAMELIST/V/X,Y,AA,AM
CALL SET(Y,6,0.)
CALL IOTA(X,12)
CALL INC(X,12,-5.)
AA=PVAL(12,AVG)
AM=PVAL(12,MULT)
WRITE(6,V)
STOP
END

FUNCTION AVG(J)
C AVG COMPUTES THE AVERAGE OF THE FIRST J ELEMENTS OF COMMON.
COMMON A(100)
AVG=0.
DO 1 I = 1,J
 1 AVG=AVG+A(I)
AVG=AVG/FLOAT(J)
RETURN
END

REAL FUNCTION MULT(J)
COMMON ARRAY(12)
MULT=ARRAY(12)*ARRAY(1)-AVG(J/2)
RETURN
END

An explanation of this example appears in part 2.
DATA STATEMENT

\[
\text{DATA (var = dlist), \ldots , (var = dlist)}
\]

\[
\text{DATA vlist/\text{dlist}_1/ , \ldots , vlist}_n/\text{dlist}_n/
\]

var Variable, array element, array name or implied DO

vlist List of array names, array elements, variable names, or an implied DO loop, separated by commas. Array elements must have integer constant subscripts, unless they appear in an implied DO loop.

dlist One or more of the following forms separated by commas:

\[
\begin{align*}
\text{constant} \\
\text{(constant list)} \\
\text{rf*constant} \\
\text{rf*(constant list)} \\
\text{rf(constant list)}
\end{align*}
\]

constant list List of constants separated by commas

rf Integer constant. The constant or constant list is repeated the number of times indicated by rf.

The DATA statement assigns to variables or array elements initial values which are compiled into the object program from source program statements. When source program execution begins, these values are assumed by the variables or arrays. Any variables not assigned values by the DATA statement are unspecified.

Example:

\[
\text{DATA A, B, C/3, 27.5, 5.0/}
\]

assigns 3. to A, 27.5 to B, 5.0 to C

The DATA statement is non-executable and should, as good programming practice, precede the first executable statement in the program or subprogram. The DATA statement must follow all specification statements. One DATA statement must not contain both forms of the list (vlist/dlist/ and var = dlist).

Dummy arguments or elements in blank common cannot be assigned values in a DATA declaration.

In the DATA statement, the type of constant stored is determined by the structure of the constant rather than by the type of the variable in the statement.
Example:

```
DATA IRUN/10./
```

10. is stored as a real constant, not as an integer, as might be expected from the form of the
symbolic name IRUN.

```
DATA ITEM, JOB/10,10./
```

An integer constant 10 is stored in ITEM, and a real constant 10. is stored in JOB. The two constants
will be stored differently:

```
0000000000000000012 integer
```

```
17235000000000000000 real
```

Any future use of the integer variable JOB could produce erroneous results.

The value of the item in the data list is assigned to the corresponding variable in the variable list. The
number of items in the data list should agree with the number of variables in the variable list.

Example:

```
DATA A,B,C/7,8,9./
```

7, 8, and 9, are assigned to A, B, and C respectively.

If the data list contains more items than the variable list, excess items are ignored, and an informative
diagnostic is printed.

Example:

```
COMMON/LABEL/A(3)
DATA A/1,2,3,4./
```

Constants 1, 2, and 3, are stored in array locations A, A+1, A+2; constant 4, is discarded; and an
informative message is printed.

If the data list contains fewer items than the variable list, the value of the remaining variable is not defined,
and an informative diagnostic is printed.

Example:

```
COMMON/NAME/C(3)
DATA C/1,2./
```

Constants 1. and 2. are stored in locations C(1) and C(2); the content of C(3), that is, location C+2
is not defined.
The implied DO loop may be used to store values into arrays.

Example:

```
REAL ANARAY(10)
DATA (ANARAY(I),I = 1,10)/1.,2.,3.,7*2.5/
```

Values stored in array ANARAY:

```
ANARAY(i)  1.
   .
   2.
   .
   3.
   .
   2.5
   .
   2.5
   .
   2.5
   .
```

When an implied DO is used to store values into arrays, only one array name can be used within the implied DO nest. The array name in the implied DO nest is not related in any way to an array of the same name in the same program unit.

Example:

Invalid:  `DATA (A(I),B(I),I=1,3)/1.,2.,3.,4.,5.,6./`

Valid:   `DATA ((C(I,J),J=1,4,3),I=1,3)/1.,2.,3.,4.,5.,6./`

Example:

```
DATA A,B,C,D/4*2.7/
```

The value 2.7 is assigned to the variable A,B,C and D. If the number preceding the asterisk is not an integer, a fatal diagnostic is printed.

The following examples illustrate the use of the DATA statement:

```
COMPLEX PROTER (4)
DATA PROTER/4*((1.0,2.0))/
```
4 complex constants (1.0,2.0) are stored in the ARRAY PROTER

1.0
2.0
1.0
2.0
1.0
2.0

Note: (1.0,2.0) is a complex constant, 2*(1.0,2.0) means repeat a constant list containing elements 1.0 and 2.0 twice, 2*((1.0,2.0)) means repeat the complex constant (1.0,2.0) twice.

Example:

DATA A(1,3)/16.239/

16.239 is stored in the element in the first row, 3rd column of array A.

DIMENSION B(10)
DATA B/000077B,000064B,3*0000005B,5*000200B/

The following octal constants are stored in ARRAY B:

77B
64B
5B
5B
5B
200B
200B
200B
200B
200B

COMMON/HERA/C(4)
DATA C/3.6,5*10.5/

ARRAY C contains the following elements:

3.6
10.5
10.5
10.5

LOGICAL L(4)
DATA L/4*.TRUE./

The logical variables in array L are set to the value .TRUE.
Examples of alternative form of DATA statement:

```plaintext
DATA (X=3),(Y=5)

INTEGER ARAY(5)
DATA (A=7),(B=200.), (ARAY=1, 2, 7, 50, 3)

COMMON/BOX/ARAY4(3,4,5)
DATA (ARAY4(1,3,5)=22.5)

DIMENSION D3(4), POQ(5,5)
DATA (D3 = 5., 6., 7., 8.), ((POQ(I,J), I=1,5), J=1,5) = 25.0
```

initializes:

```plaintext
D3(1) = 5.
D3(2) = 6.
D3(3) = 7.
D3(4) = 8.
```

and sets the entire POQ array to zero.

When constants in a data list are enclosed in parentheses and preceded by an integer constant, the list is repeated the number of times indicated by the integer constant. If the repeat constant is not an integer, a compiler error message is printed.

Example:

```plaintext
DIMENSION B(10)
DATA((B(I), I=1,10)=15., 2., 3., 7, 7(4.32))

DIMENSION AMASS(10,10,10), A(10), B(5)
DATA (AMASS(6, K, 3), K=1,10) = 4*(-2., 5.139), 6.9, 10./
DATA (A(I), I=5,7) = 2*(4.1), 5.0/
DATA B/5*0.0/

ARRAY AMASS:

<table>
<thead>
<tr>
<th>AMASS(6,1,3)</th>
<th>AMASS(6,2,3)</th>
<th>AMASS(6,3,3)</th>
<th>AMASS(6,4,3)</th>
<th>AMASS(6,5,3)</th>
<th>AMASS(6,6,3)</th>
<th>AMASS(6,7,3)</th>
<th>AMASS(6,8,3)</th>
<th>AMASS(6,9,3)</th>
<th>AMASS(6,10,3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2.</td>
<td>5.139</td>
<td>-2.</td>
<td>5.139</td>
<td>-2.</td>
<td>5.139</td>
<td>-2.</td>
<td>5.139</td>
<td>6.9</td>
<td>10.</td>
</tr>
</tbody>
</table>

ARRAY A:

<table>
<thead>
<tr>
<th>A(5)</th>
<th>A(6)</th>
<th>A(7)</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.1</td>
<td>4.1</td>
<td>5.0</td>
</tr>
</tbody>
</table>

ARRAY B:

<table>
<thead>
<tr>
<th>B(1)</th>
<th>B(2)</th>
<th>B(3)</th>
<th>B(4)</th>
<th>B(5)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>
```
Data may not be entered into blank common with a DATA statement.
When a Hollerith specification is used in a DATA statement, it should not exceed 10 characters.
For example, to store the following values in an array A

\[
\begin{align*}
A(1) &= 1234567890 \\
A(2) &= ABCDEFGHIJ \\
A(3) &= KLMNOPQRSTUVWXYZ \\
A(4) &= UVWXYZ+- *
\end{align*}
\]

The following statements should be used:

```
DIMENSION A(4)
DATA A/10H1234567890,10HABCDEFGHIJ,10HKLmnopqrstuvwxyz,10HUVWXYZ+- */
```

The following statements would not produce the desired result:

```
DIMENSION A(4)
DATA A/20H1234567890ABCDEFGHIJ,20HKLmnopqrstuvwxyzUvwxyz+- */
```

They would initialize

\[
\begin{align*}
A(1) &= 1234567890 \\
A(2) &= \text{KLMNOPQRSTUVWXYZ} \\
A(3) &= \text{UVWXYZ+- *} \\
A(4) &= \text{undefined}
\end{align*}
\]

**BLOCK DATA SUBPROGRAM**

Data may be entered into labeled or numbered common (but not blank common) prior to program execution by the use of the BLOCK DATA subprogram. This subprogram should contain only the DATA, COMMON, DIMENSION, EQUIVALENCE, type, and END statements associated with the data defined.

Any executable statements will be ignored, and a warning printed.

A BLOCK DATA subprogram has one of the following formats:

```
BLOCK DATA name
   .
   .
   .
END

BLOCK DATA
   .
   .
   .
END
```

Name is any legal FORTRAN name. It identifies the BLOCK DATA subprogram if more than one BLOCK DATA subprogram is compiled. If the user does not name the block, it is given the name BLKDATA.
DATA may be entered into more than one block of common in one subprogram.

Example:

```
    BLOCK DATA ANAME
    COMMON/CAT/X,Y,Z/DEF/R,S,T
    COMPLEX X,Y
    DATA X,Y/2*(*(1.0,2.7))/,R/7.6543/
    END
```

Z is in block CAT, and S and T are in DEF; although no initial data values are defined for them.

The DATA statement must follow the specification statements.

```
    BLOCK DATA
    COMMON/ABC/A(5),B,C/BILL/D,E,F
    COMPLEX D,E
    DOUBLE PRECISION F
    DATA (A(L),L=1,5)/2.3,3.4,3*7.1/,B/2034.756/,D,E,F/2*(*(1.0,2.5)).
    S 7.86972415872D30/
    END
```
MAIN PROGRAM AND SUBPROGRAMS

A FORTRAN program may be written with or without subprograms. One main program is required in any executable FORTRAN program; any number of subprograms may be included.

MAIN PROGRAM

A main program should begin with the PROGRAM statement. If this statement is omitted from the main program, the program is assumed to have the name START, and files INPUT and OUTPUT are assumed.

PROGRAM STATEMENT

Under the SCOPE operating system, all data used by a program must have a file name. The FORTRAN programmer should list this file name in the PROGRAM statement. The FORTRAN compiler adds the characters TAPE as a prefix to each logical unit number referenced in the user's program to form a file name. For example, logical unit 3 is assigned the file name TAPE3, and the programmer should list the file name TAPE3 in the PROGRAM statement if he references logical unit 3 in his program. SCOPE file names INPUT, OUTPUT and PUNCH should appear in the PROGRAM statement when READ, WRITE and PUNCH statements are used in a program.

The file name must appear in the PROGRAM statement of the main program even if the read or write statement is in a subprogram.

```
7
```

PROGRAM name (file, ..., file)

name

Must be a unique symbolic name within the main program and cannot be used as a subprogram name. It will be the entry point name and the object deck name for the SCOPE loader.

(file, ..., file)

Names of all input/output files required by the main program and its subprograms; maximum number of file names is 50. All internal file names used in input/output statements should be declared. If the program is to be loaded as an overlay (but not as the main overlay) this parenthetical list must be omitted.

file

1-6 character file name
file = n

n is a decimal number specifying the buffer length. It must appear with the first reference to the file in the PROGRAM statement. If no buffer length is specified, a default double buffer (2002B) is assumed. A buffer length of zero can be specified. For example, PROGRAM X (TAPE = 0) is a legal statement.

If file = n is specified in a 7600 program, it is ignored.

fileₙ = fileₘ

Files will be made equivalent. File m must have been previously defined.

File names may be made equivalent at compile time, but file m must have been previously defined in the same PROGRAM statement. All references in the source code to file n refer to file m. Since m and n refer to the same file, any buffer length specified applies to both file names.

Example:

PROGRAM ORB (INPUT, OUTPUT=1000, TAPE1=INPUT, TAPE2=OUTPUT)

All input/output statements which reference TAPE1 will instead reference INPUT, and all listable output normally recorded on TAPE2 would be transmitted to the file named OUTPUT.

Only one level of parentheses is allowed in the PROGRAM statement. The PROGRAM statement is scanned from left to right.

Example:

PROGRAM SORT (INPUT, OUTPUT, TAPE5=INPUT, COMPILE=4000, TAPE20=COMPILE)

At compile time, the file names should satisfy the following conditions (file names can be changed at execution time by SCOPE control cards). If these conditions are not met, a warning diagnostic is printed:

1. File name INPUT should be defined if any READ fn, iolist statement is included in the program.

2. File name OUTPUT should be defined if any print statement is included. If execution error messages are to be listed, OUTPUT must be included.

3. File name PUNCH should be defined if any PUNCH statement is included in the program.

4. File name TAPEu (u is an integer constant 1-99) should be defined if any input/output statement involving unit u appears in the program. At execution time, if u is a variable, there must be a file name TAPEu for each value u may assume.

At execution time, if file names have not been defined in the PROGRAM statement, they must be defined by SCOPE control cards (refer to File Name Handling by System, section 3, part 3). If they are not defined, a fatal error results and the message UNDEFINED FILE NAME is printed.
The characters TAPE are added as a prefix to each logical unit number in the user’s program. Logical unit 3 is assigned the file name TAPE3, logical unit 4 is assigned the file name TAPE4. Note, TAPE5 and TAPE05 are not the same file name.

A logical unit number is assigned by writing TAPEu = filenam, where filenam is the name of the file with which the logical unit number is to be associated.

Examples:

```plaintext
PROGRAM X (INPUT, TAPE5=INPUT)
PROGRAM Y (OUTPUT, TAPE2=OUTPUT)
PROGRAM OUT(OUTPUT, TAPE6=OUTPUT)
.
.
WRITE(6,200)A,B,C           Logical unit 6 must be declared as TAPE6
200 FORMAT (1H1,3F7.3)       in the PROGRAM statement.

PROGRAM IN(INPUT, TAPE5=INPUT)
.
.
READ(5,100)A,B,C            This statement reads from logical unit 5,
100 FORMAT (3F7.3)           it is declared in the PROGRAM statement
                             as TAPE5.
```

When a file name is made equivalent to another file, the file name appearing to the right of an equals sign must have been previously declared in the same statement.

Example:

In the following statement, INPUT and OUTPUT are defined before they appear to the right of the equals sign. TAPE5 becomes an alternate name for the file INPUT, and TAPE6 becomes an alternate name for OUTPUT.

```plaintext
PROGRAM SAMPLE (INPUT, OUTPUT, TAPE5=INPUT, TAPE6=OUTPUT)
```

Example:

```plaintext
PROGRAM JIM(INPUT, TAPE19=INPUT)
TAPE19=INPUT must be preceded in the same statement by INPUT (or INPUT = buffer length)
```
If any of the following statements are used in a program or its subprograms, the logical unit number, u, must appear as file name TAPEu in the program statement:

\begin{align*}
&\text{WRITE (u) iolist} & &\text{ENDFILE u} \\
&\text{WRITE (u,fn) iolist} & &\text{BACKSPACE u} \\
&\text{READ (u) iolist} & &\text{REWIND u} \\
&\text{READ (u,fn) iolist} & &\text{BUFFER IN (u,p) (a,b)} \\
& & &\text{BUFFER OUT (u,p) (a,b)}
\end{align*}

If u is a variable, there must be a file name TAPEu for each value u can assume in the source program.

Example:

\begin{verbatim}
PROGRAM KAY(INPUT,OUTPUT,TAPE60=INPUT,TAPE61=OUTPUT)
  .
  .
  READ(60,100)ALIST
  100 FORMAT (F7.3)
  .
  .
  WRITE (61,200)ALIST
  200 FORMAT (1HO,F7.3)
\end{verbatim}

Example:

\begin{verbatim}
PROGRAM JEX(TAPE1,TAPE2,TAPE3,TAPE4)
  .
  .
  N=2
  .
  .
  READ(N)
  .
  .
  N=2+1
  .
  .
  READ(N)
\end{verbatim}

**SUBPROGRAMS**

A subprogram is headed by a BLOCK DATA, FUNCTION, or SUBROUTINE statement. A subprogram headed by a BLOCK DATA statement is a specification subprogram as described in Section 6. A subprogram headed by a FUNCTION or SUBROUTINE statement is called a procedure subprogram.
Procedure subprograms are of two types: subroutine and function. Function subprograms return a single value to the expression containing the function’s name. The four kinds of functions are:

Statement functions
FUNCTION subprograms
Intrinsic functions (in-line functions)
library functions

user defined
system supplied

Subroutine subprograms may return a number of values (or none at all); they are referenced by a CALL statement. The two kinds of subroutines are:

User subroutine

Library subroutine

Subprograms are defined separately from the calling program and may be compiled independently of the main program. They are complete program units conforming to all the rules of FORTRAN programs. The term program unit refers to either a main program or a subprogram.

A subprogram may call other subprograms as long as it does not directly or indirectly call itself. For example, if program A calls program B, B may not call A. A calling program is a program unit which calls a subprogram.

Subprogram definition statements declare certain names to be dummies representing the arguments of the subprogram—these are called dummy arguments. They are used as ordinary names within the defining subprogram and indicate the number, type and order of the arguments and how they are used. The dummy arguments are replaced by the actual arguments when the subprogram is executed. Dummy arguments may not appear in COMMON, EQUIVALENCE, or DATA statements.

Actual parameters appear in subroutine calls

CALL SUB3 (7.,CAT, 8.932)

or function references

\[ A = B + \text{ROOT}(6.5,7.,30X) \]
FUNCTION SUBPROGRAM

DEFINING A FUNCTION SUBPROGRAM

\[
\text{FUNCTION name } (p_1, \ldots, p_n)
\]

\[
\text{type FUNCTION name } (p_1, \ldots, p_n)
\]

\[p_1, \ldots, p_n\] Dummy arguments which should agree in order, number, and type with the actual arguments in the calling program. At least one argument is required; a maximum of 63 is allowed.

type The type may be REAL, INTEGER, DOUBLE PRECISION, (the word PRECISION is optional), COMPLEX or LOGICAL. When type is omitted, and no IMPLICIT statement appears in that program unit, the type of the function result is determined by the first character of the function name.

name FUNCTION name. It must not appear in any non-executable statement other than the FUNCTION statement in the subprogram.

Dummy arguments may be the names of arrays, variables, and subprograms. Since all names are local to the subprogram containing them, dummy arguments may be the same as names appearing outside the subprogram. A dummy argument must not appear in COMMON, EQUIVALENCE or DATA statements within the function subprogram.

The programmer can define a sequence of statements as a function. A function subprogram begins with a FUNCTION declaration and returns control to the calling program when a RETURN statement in the function subprogram is encountered. Execution of the FUNCTION subprogram results in a single value which is returned to the main program through the function name.

The name of the function must be assigned a value within the function subprogram; if it is not assigned a value, a warning diagnostic is printed. This value is the value of the function.

If an END statement is encountered in the FUNCTION subprogram, a RETURN is assumed.

A function must not, directly or indirectly reference itself.

FUNCTION SUBPROGRAM REFERENCE

A function is referenced when the name of a function appears in an arithmetic, logical or masking expression. A function reference transfers control to the function subprogram, and the values of the actual arguments are substituted for the dummy arguments.
Actual arguments may be arithmetic or logical expressions, constants, variables, array names, array element names, SUBROUTINE subprogram names, an external function name (not an intrinsic function or statement function), or function reference (the function reference is a special case of an arithmetic expression), or a Hollerith constant, or an ECS variable, array or array element name, or an LCM variable, array name or array element name.

Example:

```
FUNCTION GRATER(A,B)
  IF (A.GT.B)1,2
  1 GRATER=A-B
  RETURN
  2 GRATER=A+B
  RETURN
END
```

When a RETURN statement in the function subprogram is executed, and control is returned to the statement containing the function reference, if A is greater than B the value of A-B, in this case, C-D-3*AX/BX is returned to the main program and used in the evaluation of the expression. If A is less than B, the value of A+B (C-D+3*AX/BX) is returned to the main program.

A function reference may appear anywhere in an expression that an operand may be used.

The name of a function must not appear in a DIMENSION declaration. Dummy arguments representing array names must appear within the subprogram in a DIMENSION or type statement giving dimension information. If dummy arguments are not dimensioned, they cannot be referenced as an array in the subprogram.

If the subscripts of an array in the subprogram are to agree with the subscripts in the calling program, the dimensions in the subprogram must be the same as those in the calling routine. If array dimensions between subprogram and calling program differ, the user must be aware of the arrangement of arrays in storage (Common, section 6 and Arrays, section 2).

Example:

```
FUNCTION DIAG (A,N)
  DIMENSION A(5,5)
  DIAG=A(1,1)
  DO 70 I=1,N
  70 DIAG=DIAG*A(I,I)
  RETURN
END
```

The function subprogram may contain any statements except PROGRAM, BLOCK DATA, SUBROUTINE, another FUNCTION statement, or any statement that directly or indirectly references the function being defined.
The FUNCTION subprogram can define or redefine one or more of its arguments to return results (as well as the value of the function) to the calling program.

Adjustable dimensions are permitted in FUNCTION subprograms.

If an actual argument is an external function name or a subroutine name, the corresponding dummy argument must be used as an external function or a subroutine name.

CONFLICTS WITH LIBRARY NAMES

If the user writes a FUNCTION subprogram with the same name as a library or intrinsic function, he should be aware of two function properties:

- Library external and intrinsic functions are implicitly typed.
- Basic external functions may be called by value.

The FORTRAN library is listed in section 8. FORTRAN Extended provides functions additional to those specified in ANSI.

Library function names are implicitly typed. For example, DSIN and DSQRT are type DOUBLE PRECISION. If the user writes a function with the name DSIN, his function will override the library function DSIN; but it is taken as type DOUBLE PRECISION in the calling program unit unless a different type is specified. The types of all external functions are listed in section 8.

Any user written function which has the same name as a basic external function, and is called by value, must appear in an EXTERNAL statement in the calling program unit. The list of external functions called by value appear in table 8-2 in section 8.

CALL BY NAME AND CALL BY VALUE

To increase speed, arguments to library functions are normally passed to subprograms by placing their values in the registers. This method is call by value. For user defined subprograms, the address of the arguments are passed to the subprogram. This method is call by name. A user supplied external function is always called by name. When the control card options T, D, or OPT=0 are specified on the control card, library subprograms are called by name also.

If the user defines a function with the same name as a basic external function, the name of his function overrides the library function, and the user function is referenced. However, the name still retains the type of the library external function and the call-by-value property. Therefore, unless the user defined function appears in an EXTERNAL statement, results may be undefined.

For example, the situation could arise where a user, having defined a function which has the same name as a library function, debugs his program using the call-by-name option T. During the debug phase no problem would arise. However, after the program is debugged, he might select the call-by-value option for faster object code; at this point, results would be undefined.
If the name of an intrinsic function is used in any context other than a function reference, the user’s definition overrides the system definition. However, a user supplied FUNCTION subprogram with the same name as an intrinsic function will be ignored, and the intrinsic function is used if the name does not appear in a type statement which differs from the type of the intrinsic function or in an EXTERNAL statement in the calling program.

**STATEMENT FUNCTION**

**DEFINING A STATEMENT FUNCTION**

```
    name (p_1, p_2, p_3, ..., p_n) = expression
```

- **name**
  Type of the function is determined by the type of the function name, unless it appears in a type statement.

- **p_1, ..., p_n**
  Dummy arguments must be simple variable names. At least one argument is required; a maximum of 63 is allowed. These arguments should agree in order, number, and type with the actual arguments used in the function reference.

- **expression**
  Any arithmetic, masking, relational, or logical expression may be used. It may contain references to library functions, statement functions, or function subprograms. Names in the expression which do not represent arguments have the same value as they have outside the function (they are normal variables).

The definition of a statement function is contained in a single statement, and it applies only to the program or subprogram containing the definition. It consists of one statement and produces only one result.

Statement function names must not appear in DIMENSION, EQUIVALENCE, COMMON or EXTERNAL statements; they can appear in a type declaration but cannot be dimensioned. Statement function names must not appear as actual or dummy arguments. If the function name is type logical, the expression must be logical. For other types, if the function name and expression differ, conversion is performed as part of the function.

A statement function must precede the first executable statement and it must follow all specification statements (DIMENSION, type, etc.). A statement function must not reference itself. For example, 
\[
R(I) = R(I) \times R(I-1)
\] is illegal unless R is an array name.
Examples:

```
LOGICAL C,P,EQV
EQV(C,P) = (C.AND.P).OR(.NOT.C.AND..NOT.P)
```

```
COMPLEX Z,F(10,10)
Z(A,I) = (3.2,0.9)*EXP(A)*SIN(A)+(2.0,1.)*EXP(Y)*COS(B)+F(I,J)
```

```
GROS(R,HRS,OTHERS) = R*HRS + R*.5*OTHERS
```

**STATEMENT FUNCTION REFERENCE**

The statement function only defines the function; it does not result in any computation.

The value of the function is computed using the values of the actual arguments. The actual arguments are substituted when a statement function reference is made; they may be any arithmetic expressions. Statement function names should not appear in an EXTERNAL statement.

For example, to compute one root of the quadratic equation \(ax^2 + bx + c = 0\), given values of \(a\), \(b\) and \(c\), an arithmetic statement function can be defined as follows:

```
ROOT (A,B,C)=(-B+SQRT(B*B-4.*A*C))/(2.*A)
```

When the function is used in an expression, actual arguments are substituted for the dummy arguments \(A,B,C\).

```
RESA = ROOT (6.5,7.,1.)
```

is equivalent to writing

```
RESA = (-7.+SQRT(7.*7.-4.*6.5*1.0))/(2.*6.5)
```

or

```
TAB = 3.7 * ROOT (CAT, 8.2, TEMP) + BILL
```

Wherever the statement function \(ROOT (A,B,C)\) is referenced, the definition of that function—in this case \((-B+SQRT(B*B-4.*A*C))/(2.*A)\)—is evaluated using the current values of the arguments \(A,B,C\).
Examples:

<table>
<thead>
<tr>
<th>Statement Function Definitions</th>
<th>Statement Function References</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD(X,Y,C,D)=X+Y+C+D</td>
<td>RES1=GROSS=ADD(TAX,FICA,INS,RES3)</td>
</tr>
<tr>
<td>AVERAGE(O,P,Q,R)-(O+P+Q+R)/4</td>
<td>GRADE=AVERAGE(TEST1,TEST2,TEST3,</td>
</tr>
<tr>
<td></td>
<td>TEST4)→MID</td>
</tr>
<tr>
<td>LOGICAL A,B,EQV</td>
<td>TEST=EQV(MAX,MIN).AND.ZED</td>
</tr>
<tr>
<td>EQV(A,B)=(A.AND.B).OR.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(.NOT.A.AND..NOT.B)</td>
</tr>
<tr>
<td>COMPLEX Z</td>
<td>RESULT=(Z(BETZ,GAMMA(I+K))**2-1.)</td>
</tr>
<tr>
<td>Z(X,Y)=(1..O.)*EXP(X)*COS(Y)</td>
<td>/SQR(TWOPIE)</td>
</tr>
<tr>
<td></td>
<td>+(O..1.)*EXP(X)*SIN(Y)</td>
</tr>
</tbody>
</table>

Here, the statement function is used to substitute a library function name in a program containing an alternate name for this library function.

\[
\text{SINF}(X)=\sin(X) \quad \text{statement function definition}
\]

\[
A=\text{SINF}(3.0+B)+7.
\]

The above sequence generates exactly the same object code as:

\[
A=\text{SINF}(3.0+B)+7.
\]

During compilation, the statement function definition is retained by the compiler. Whenever the function is referenced, instructions are generated in line to evaluate the function (as opposed to FUNCTION subprograms for which a branch instruction is generated at each reference). The expansion of a statement function is similar to the expansion of an assembly language macro. Thus the statement function does not reduce execution speed or efficiency.
SUBROUTINE SUBPROGRAMS

DEFINING A SUBROUTINE SUBPROGRAM

SUBROUTINE name \( \{ p_1, p_2, \ldots, p_n \} \)

SUBROUTINE name

SUBROUTINE name \( \{ p_1, p_2, \ldots, p_n \} \), RETURNS \( \{ b_1, b_2, \ldots, b_n \} \)

name                 Symbolic name of the SUBROUTINE

\( p_1, \ldots, p_n \) Dummy arguments which must agree in order, number and type with the actual arguments passed to the subprogram at run time. A maximum of 63 is allowed. The argument list is optional. Dummy arguments can be the names of arrays, simple variables, library functions, or subprograms. Since dummy arguments are local to the subprogram containing them, they may be the same as names appearing outside the subprogram. A dummy argument must not appear in a COMMON, EQUIVALENCE, or DATA statement within the subroutine.

\( b_1, \ldots, b_n \) Dummy statement numbers which must agree in order and number with the actual statement numbers passed to the SUBROUTINE. The variables \( b_1, \ldots, b_n \) are defined in the SUBROUTINE.

A SUBROUTINE subprogram can be referred to only by a CALL statement. It starts with a SUBROUTINE statement and returns control to the calling program through one or more RETURN statements. The subprogram name is not used to return results to the calling program and does not determine the type of the subprogram. Values are passed by one or more arguments or through common (refer to SUBPROGRAMS and COMMON).

Dummy arguments which represent array names must be dimensioned within the subprogram by a DIMENSION or type statement. If an array name without subscripts is used as an actual argument in a CALL statement and the corresponding dummy argument has not been declared an array in the subprogram, the first element of the array is used in the subprogram. Adjustable dimensions are permitted in SUBROUTINE subprograms.
SUBROUTINE subprograms do not require a RETURN statement if the procedure is completed upon executing the END statement. When the END line is encountered, a RETURN is implied.

SUBROUTINE subprograms may contain any statements except PROGRAM, BLOCK DATA, FUNCTION, or another SUBROUTINE statement.

The SUBROUTINE name must not appear in any other statement in the same subprogram.

Example:

Calling Program                     Subprogram

.                                  SUBROUTINE PGM1(X,Y,Z),
.                                  XRETURNS (M,N)
.                                  U=X**Y
CALL PGM1(A,B,C),                X=Z+X**Y
XRETURNS (5,10)                   20 IF (U-X) 25, 30, 35
.                                  25 RETURN M       Return is to statement 5 in calling program
.                                  30 RETURN N       Return is to statement 10 in calling program
5 B=SQR(A*C)                      35 Z=Z+(X*Y)
.                                  RETURN
.                                  END

10 CALL PGM2 (D,E)                
.                                  
.                                  

The above example illustrates the different types of returns possible from a subroutine subprogram. If the RETURNS list is omitted from the CALL statement in the calling program, the form RETURN i may not be used. The converse is permitted however, a normal return via the RETURN statement may be made to the calling program if the RETURNS list is specified in the CALL statement.

The RETURN statement is described in section 5.
REFERENCING A SUBROUTINE SUBPROGRAM

CALL STATEMENT

The CALL statement causes a SUBROUTINE subprogram to be executed.

name  Name of subroutine called must not appear in any specification statement in the calling program except an EXTERNAL statement.

$p_1$,...,$p_n$  Actual arguments which must correspond in order, number, and type with those specified in the SUBROUTINE statement.

$b_1$,...,$b_m$  Numbers of statements in the calling program or subprogram to which control returns. They correspond in order and number with the dummy statement numbers in the subroutine. If alternate exits are taken from the subroutine, $b_1$,...,$b_m$ must be specified. Otherwise, this specification can be omitted, and control returns to the statement immediately following the CALL.

The total number of arguments, $p_1$,...,$p_n$ + $b_1$,...,$b_m$, must not exceed 63.

Actual arguments may be: arithmetic or logical expressions, constants, variables, array elements, array names, library function names, subroutine subprogram names, external function names (not an intrinsic or statement function), function references (the function reference is a special case of an arithmetic expression), or LEVEL 3 array names or variables.
Example:

PROGRAM MAIN(INPUT, OUTPUT)
   .
   .
   10 CALL XCOMP(A, B, C), RETURNS(101, 102, 103, 104)
   .
   .
   101 CONTINUE
   .
   .
   GO TO 10
   102 CONTINUE
   .
   .
   .
   GO TO 10
   103 CONTINUE
   .
   .
   .
   GO TO 10
   104 CONTINUE
   END

SUBROUTINE XCOMP (B1, B2, C), RETURNS(A1, A2, A3, A4)
   IF(B1 * B2 < 4.159) 10, 20, 30
   10 CONTINUE
   .
   .
   RETURN A1
   20 CONTINUE
   .
   .
   RETURN A2
   30 CONTINUE
   .
   .
   IF (B1) 40, 50
   40 RETURN A3
   50 RETURN A4
   END
PROGRAM VARDIM (OUTPUT, TAPE6=OUTPUT)
COMMON X(4,3)
REAL Y(6)
CALL IOTA(X, 12)
CALL IOTA(Y, 6)
WRITE (6,100) X, Y
100 FORMAT (*1ARRAY X = *, 12F6.0, 5X, *ARRAY Y = *, 6F6.0)
STOP
END

SUBROUTINE IOTA (A, M)
C IOTA STORES CONSECUTIVE INTEGERS IN EVERY ELEMENT OF THE ARRAY A
C STARTING AT I
DIMENSION A(M)
DO 1 I = 1, M
1 A(I) = I
RETURN
END

If a CALL is the last statement in a DO loop, looping continues until the DO loop is satisfied.

Example:

Calling Program                                Subprogram
DO 5 I = 1, 20
   ..
5   CALL GRATER (STACK(I), TEMP(I))
   ..

SUBROUTINE GRATER (A, B)
   IF (A .GT. B) 1, 2
1   B = A - B
   RETURN
2   B = A + B
   RETURN
END

The subroutine subprogram GRATER will be called 20 times.

Example:

Calling Program                                Subprogram
..                                               SUBROUTINE SORT(ALIST)
..                                               INTEGER ALIST (50)
..                                               DO 10 J = 1, 50
..                                               K = 50 - J
..                                               DO 10 I = 1, K
..                                               CALL SORT (LIST)
..                                               IF (ALIST (I) - ALIST (I+1)) 15, 10
.                                               15   ITEMP = ALIST (I)
.                                               ALIST (I) = ALIST (I + 1)
.                                               ALIST (I + 1) = ITEMP
10 CONTINUE
50 WRITE (6, 200) ALIST
200 FORMAT (*1", 10(I4, 2X))
RETURN
END

The parameter list in a SUBROUTINE subprogram is optional.
Example:

<table>
<thead>
<tr>
<th>Calling Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SUBROUTINE ERROR1</td>
</tr>
<tr>
<td></td>
<td>WRITE (6,1)</td>
</tr>
<tr>
<td></td>
<td>1 FORMAT (5X,&quot;NUMBER IS OUT OF RANGE&quot;)</td>
</tr>
<tr>
<td>IF (A-B) 10,20,20</td>
<td>RETURN</td>
</tr>
<tr>
<td></td>
<td>END</td>
</tr>
<tr>
<td>10 CALL ERROR1</td>
<td></td>
</tr>
<tr>
<td>20 RESULT-(A*C) +375.2-ZERO</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

SUBPROGRAMS AND COMMON

Transferring values through common is a more efficient method of passing values than through arguments in the CALL statement. Variables or arrays in a calling program or a subprogram can share the same storage locations with variables or arrays in other subprograms. Therefore, a block of common storage can be used to transfer values between a calling program and a subprogram.

Example:

```
PROGRAM CMN (INPUT, OUTPUT)
COMMON NED (10)
READ 3,NED
3 FORMAT (10I3)
CALL JAVG
STOP
END
SUBROUTINE JAVG
C THIS SUBROUTINE COMPUTES THE AVERAGE OF THE FIRST 10 ELEMENTS IN
C COMMON
COMMON N(10)
ISTORE = 0
DO 1 I = 1,10
  1 ISTORE = ISTORE * N(I)
ISTORE = ISTORE/10
PRINT 2,ISTORE
2 FORMAT (*1AVERAGE = *I10)
RETURN
END

AVERAGE = 45
```
The array NED in program CMN and the array N in subroutine JAVG share the same locations in common. NED(1) shares the same location with N(1), NED(2) with N(2), etc. The values read into locations NED(1) through NED(10) are available to subroutine JAVG. JAVG computes and prints the average of these values.

Arguments passed in COMMON are subject to the same rules with regard to type, length, etc., as those passed in an argument list (section 5).

ADJUSTABLE DIMENSIONS IN SUBPROGRAMS

Within a subprogram, array dimension specifications may use integer variables instead of constants, provided the array name and all integer names used for array dimension specifications are dummy arguments of the subprogram. The actual array name and values for the dummy variables are given by the calling program when the subprogram is called. The dimensions of a dummy array in a subprogram are adjustable and may change each time the subprogram is called; however, the absolute dimensions of the array must have been declared in a calling program. The size of an array passed to a subprogram using adjustable dimensions should not exceed the absolute dimensions of that array.

Adjustable dimensions cannot be used for arrays which are in common.

Calling Program

| DIMENSION A(10,10),B(10,10),C(10,10), |
| S E(5,5),F(5,5),G(5,5),H(10,10) |
| CALL MATADD(E,F,G,5,5) |
| CALL MATADD(A,B,C,10,7) |

SUBROUTINE Subprogram

| SUBROUTINE MATADD(X,Y,Z,M,N) |
| DIMENSION X(M,N),Y(M,N),Z(M,N) |
| DO 10 I = 1,M |
| DO 10 J = 1,N |
| 10 Z(I,J) = X(I,J) + Y(I,J) |
| RETURN |
| END |

CALL MATADD(A,B,C,10,7) When this call is made to the subprogram, the actual arguments (A,B,C,10,7) are substituted for MATADD(X,Y,Z,M,N), and the subprogram is assigned dimensions: DIMENSION X(10,7),Y(10,7),Z(10,7)

The main program may call the subroutine MATADD from several places within the main program.

The adjustable dimensions may be passed through more than one level of subprograms.
Example:

Calling Program

```
SUBROUTINE SUB3 (B,I,J)
DIMENSION B(I,J)

REAL A(10,5)
CALL SUB3 (A,5,3)
```

Subprogram

```
SUBROUTINE SUB4 (B,I,J)
```

In the main program, array A has dimensions (10,5); a portion of this array is passed to the subroutine SUB3 through the call CALL SUB3(A,5,3). Thus array B in the subroutine has dimensions (5,3). The subroutine SUB3, in turn, calls another subroutine SUB4 passing the dimensions of the array B. The array X in the subroutine SUB4 has dimensions X(5,3).

Constants must be used when array A is dimensioned in the initial calling program, and the values of second and third arguments in the subprogram call should be consistent with the dimensions of A. If adjustable dimensions are not consistent with constant dimensions in the calling program, results are undefined.

In a subprogram, an array name which appears in a COMMON statement must not have adjustable dimensions.

Example:

```
PROGRAM VARDIM (OUTPUT,TAPE6=OUTPUT)
COMMON X(4,3)
REAL Y(6)
CALL IOTA(X,12)
CALL IOTA(Y,6)
WRITE (6,100) X,Y
100 FORMAT (*1ARRAY X = *,12F6.0,5X,*ARRAY Y = *6F6.0)
STOP
END
```

C IOTA STORES CONSECUTIVE INTEGERS IN EVERY ELEMENT OF THE ARRAY A
C STARTING AT 1
DIMENSION A(M)
DO 1 I = 1,M
  1 A(I)=I
RETURN
ENTRY STATEMENT

A subroutine or function subprogram may be entered at a point other than the first executable statement through the ENTRY statement.

In the subprogram, name may appear only in the ENTRY statement. The first executable statement following ENTRY becomes an alternate entry point to the subprogram. An ENTRY statement in a main program is ignored, and a warning diagnostic is printed.

Example:

Main Program

```
COMMON SET1 (25)
  .
  .
  CALL CLEAR (SET1) 100 ARAY (I) = 0.0
  .
  ENTRY FILL
  .
  3 READ 2, VALUE, IPLACE Entry Point
  .
  2 FORMAT (10X, F7.2, 14)
  CALL FILL
  ARAY (IPLACE) = VALUE
  .
  IF (IPLACE .GT. 24) RETURN
  .
  GO TO 3
  .
  END
```

Subroutine Subprogram

```
SUBROUTINE CLEAR (ARAY)
  DIMENSION ARAY (25)
  DO 100 I = 1, 25 Entry Point
  100 ENTRY FILL
```

At some point in the main program, a call is made to the subroutine: CALL CLEAR (SET1)

The array SET1 is set to zero and values are read into the array. Later in the program, a call is made again to the subroutine CLEAR; but this time it is entered at the entry point FILL: CALL FILL

When FILL is called, further values are read into the array SET1 without first setting the array to zero.

Each ENTRY name must appear in a separate ENTRY statement. ENTRY statements should not have statement labels; if a statement label appears, it is ignored and a warning diagnostic is printed. The ENTRY statement does not have any arguments; the dummy arguments appearing with the FUNCTION or SUBROUTINE statement are implied. A subroutine or function subprogram can contain any number of ENTRY statements.

The ENTRY statement may appear anywhere in the subprogram except within a DO loop. Within a DO loop, it is ignored and a warning diagnostic is printed. The ENTRY statement is referenced in the same way a SUBROUTINE or FUNCTION is referenced.
Example:

**Main Program**

\[ Z = A + B - J O E (3.5 P, Q - 1) \]

\[ R = S + J A M (Q, 2.5 P) \]

**Function Subprogram**

\[ \text{FUNCTION} \ J O E (X, Y) \]

\[ 10 \ \text{JOE} = X + Y \]

\[ \text{RETURN} \]

\[ \text{ENTRY} \ J A M \]

\[ \text{IF} (X, \text{GT}, Y) 10, 20 \]

\[ 20 \ \text{JOE} = X - Y \]

\[ \text{RETURN} \]

\[ \text{END} \]

In the calling program, an entry name may appear in an `EXTERNAL` statement, and `FUNCTION` entry names also may appear in type statements. All `ENTRY` points within a `SUBROUTINE` subprogram define `SUBROUTINE` subprogram names, and all `ENTRY` points within a `FUNCTION` subprogram define `FUNCTION` subprogram names. A function entry name assumes the same type as the name in the `FUNCTION` statement.

Example:

**Main Program**

\[ \text{REAL} \ \text{JOHN} \]

\[ R = A + \text{JOHN}(8, 7) \]

**Function Subprogram**

\[ \text{FUNCTION} \ \text{TED} (X, Y) \]

\[ \text{DO} 20 \text{N} = 1, 10 \]

\[ 20 \ \text{TED} = Y + 3.7 \times X \]

\[ \text{ENTRY} \ \text{JOHN} \]

\[ \text{READ} 4, \text{NUM}, \text{IFOR} \]

\[ 4 \ \text{FORMAT} (5 X, 6 I 6) \]

\[ \text{JOHN} = \text{NUM} + \text{IFOR} * 20 \]

\[ \text{RETURN} \]

\[ \text{END} \]

The name of the `FUNCTION` is implicitly typed real, therefore, `JOHN` assumes the type real. `JOHN` should be declared real in the calling program.

An `ENTRY` name must be unique in the `FUNCTION` subprogram.

Example:

\[ \text{FUNCTION} \ \text{CAT}(A, B) \]

\[ \text{DOG} = 10.5 + 3.2 \]

\[ \text{ENTRY} \ \text{DOG} \]

The `ENTRY` name `DOG` is not valid because it has been used as a variable.
The value of the function is the last value assigned to the name of the function regardless of which ENTRY statement was used to enter the subprogram. The function name is used to return results to the calling program even though the reference was through an entry name.

Example:

Calling Program

```
RESULT=FSHUN(X,Y,Z)
RES2=FRED(R,S,T)
```

Subprogram

```
FUNCTION FSHUN(A,B,C)
  3  FSHUN=A*B/C**2
  RETURN
ENTRY FRED
IF(A .LE. 702.) GO TO 3
  FSHUN=(C+A)/B
  RETURN
END
```

When the FUNCTION FSHUN is entered at the beginning of the function, or through the ENTRY FRED, the result must be returned to the calling program through the function name FSHUN.

Example:

```
SUBROUTINE SET (A,M,V)
C       SET PUTS THE VALUE V INTO EVERY ELEMENT OF THE ARRAY A
DIMENSION A(M)
D011=1*M
1  A(I)=0.0
C
ENTRY INC
C       INC ADDS THE VALUE V TO EVERY ELEMENT IN THE ARRAY A
DO 2 I = 1,M
2  A(I) = A(I) + V
RETURN
END
```

An explanation of this example appears in part 2.
Certain subprograms that are of general utility or difficult to express in FORTRAN are supplied by the system. These library subprograms are referenced with a CALL statement or a function reference in exactly the same way a user written subprogram is referenced. The library provides:

**External Functions.** When an external function is referenced in a source program, a call is made to a library function, and the required result is returned to the user's program.

**Intrinsic Functions.** When the user references an intrinsic function, the compiler inserts code in-line in the object code of the source program unless the T, D, or OPT=0 option is selected on the FTN control card, or the name of the function appears in an EXTERNAL statement.

**Utility Subprograms.** In addition to the basic external functions and intrinsic functions specified by ANSI, the FORTRAN library contains additional utility subprograms for the user's convenience. Utility subprograms are always called by name (refer to section 7).

When a user defined external function has the same name as a library intrinsic function, the library function is referenced and the user defined function is ignored. However, a user defined function with the same name as a library external function overrides the library function.

**INTRANISIC FUNCTIONS**

If an intrinsic function name is used in any context other than a function reference, the user definition overrides the system definition. An intrinsic function name may be used as:

- Variable
- Array name
- Statement function name
- Name of a FUNCTION subprogram — only if it appears in a type statement of a different type or in an EXTERNAL statement.

Intrinsic function names should not be used for a user defined function name (unless they appear in an EXTERNAL or type statement). Otherwise, the user defined function will be ignored. (Refer to section 7).

If the control card options T, D, or OPT=0 are specified, intrinsic functions are called by name.

A list of the intrinsic functions defined in ANSI and the additional intrinsic functions provided by FORTRAN Extended follows. Non-ANSI intrinsic functions appear in blue type.

If a function has no mode, the result of the function assumes the type of the expression in which it is used. The functions SIGN, ISIGN, and DSIGN are defined when the value of the second argument is zero, such that the sign of the second argument is taken as positive for +0 and negative for -0. The functions AMOD and MOD are not defined, however, when the second argument is zero; division by zero renders the results undefined.

EXTERNAL FUNCTIONS

In the following list of basic external functions defined in ANSI and the additional external functions provided by FORTRAN Extended, non-ANSI functions appear in blue type.

External functions are called by value if the control card option T, D or OPT=0 is not specified and they do not appear in an EXTERNAL statement.

If the user defines a function with the same name as a library external function, his function overrides the library function. The name still retains the type of the library external function, however, and it will be called by value (if the control card option T, D, or OPT=0 is not selected) unless declared EXTERNAL. Therefore, if a user defined function has the same name as a library function, that name should appear in a type or EXTERNAL statement. (Refer to section 7 for an explanation of call-by-value).

In the following tables, A represents the argument. When more than one argument is involved, A1 is the first argument and A2 the second. Arguments may not be used for which a result is not mathematically defined, and they may not be of a type other than that specified.

† The function DMOD (x1,x2) is defined as x1−|x1/x2| x2, where |x| is the largest integer that does not exceed the magnitude of x with sign the same as x.
ADDITIONAL UTILITY SUBPROGRAMS

The following utility subroutines are supplied by the system. ANSI does not specify any library subroutines.

A user supplied subprogram with the same name as a library subprogram overrides the library subprogram, but still retains the type of the library subprogram.

The subprograms which follow are always called by name (refer to section 7).

In the following definitions, i is an integer variable or constant; j is an integer variable.

SUBROUTINES

CALL DUMP (a_i,b_i,f_1,...,a_n,b_n,f_n)
CALL PDUMP (a_i,b_i,f_1,...,a_n,b_n,f_n)

Dumps central memory (small core storage) on the OUTPUT file in the indicated format. If PDUMP was called, it returns control to the calling program; if DUMP was called, it terminates program execution. a_i identifies the first word and b_i the last word of the storage area to be dumped; 1 ≤ n ≤ 20. f is a format indicator, as follows:

f = 0 or 3, octal dump
f = 1, real dump
f = 2, integer dump
f = 4, octal dump

a and b indicate the range of addresses to dump rather than specific addresses, therefore, if statement labels are specified, an ASSIGN statement must be used to define a and b. A dump begins at the statement assigned to a_i, and ends with the statement number assigned to b_i.

The maximum number of arguments is 63.

Example:

CALL PDUMP (A,B,O,M,N,4,X,X(100),1)

CALL SSWITCH (i,j)

If sense switch i is on, j is set to 1; if sense switch i is off, j is set to 2. i is 1 to 6. If i is out of range, an informative diagnostic is printed, and j = 2. The computer operator uses this subroutine to select options in a FORTRAN program.

CALL REMARK (H)

Places a message of not more than 40 characters, in the dayfile. H is a Hollerith specification.

Example:

CALL REMARK (9HLAST DECK)
CALL DISPLA (H,k)
Displays a name and a value in the dayfile. H is a Hollerith specification of not more than 40 characters, k is a variable, or a real or integer expression; k is displayed as an integer or real value.

Example: CALL DISPLA (7H TIME -, STOP-START)

CALL RANGET(n)
Obtains current generative value of RANF between 0 and 1. n is a symbolic name to receive the seed. It is not normalized.

CALL RANSET(n)
Initializes generative value of RANF. n is a bit pattern. Bit 2^n will be set to 1 (forced odd), and bits (2^59-2^48) will be set to 1717 octal.

SECOND(t) or CALL SECOND (t)†
Returns central processor time from start of job in seconds, in floating point format, accurate to three decimal places. t is a real variable.

Example: DPTIM = SECOND (CP)

DATE(a) or CALL DATE (a)†
The value of a will be the current date in operating system format. a is a dummy argument. Format is bMM/DD/YYb; but it may vary at installation option.

Examples: TODAY = DATE (D)
CALL DATE (TODAY)

†These routines can be used as functions or subroutines. The value is always returned via the argument and the normal function return.
TIME(a) or CALL TIME (a)†

The value of a will be the current reading of the system clock. Format is HH.MM.SS.

Examples:

TYM = TIME (C)

CALL TIME (C)

CALL ERRSET (a,b)††

Sets maximum number of errors, b, allowed in input data before fatal termination. Error count is kept in a.

CALL LABEL (u,fwa)††

Sets tape label information for a file. u is the unit number. fwa is the address of the first word of the label information. The label information must be in the mode and format discussed in the SCOPE Reference Manual.

CALL MOVLEV (a,b,n)

Transfers n consecutive words of data between a and b. a and b are variables or array elements; n is an integer constant or expression. a is the starting address of the data to be moved and b is the starting address of the location to receive it.

Example:

CALL MOVLEV(A,B,1000)

CALL OPENMS (u,ix,lngth,t)†††

Opens mass storage file and informs Record Manager that this file is word addressable. If an existing file is called, the master index is read into the area specified by the program. u is the unit designator. ix is the first word address of the index in central memory. lngth is the length of the index buffer; for a name index, lngth ≥ 2 * (number of records in file) + 1; for a number index, lngth ≥ number of records in file + 1. t = 1 file is referenced through a name index; t = 0 file is referenced through a number index.

Example:

PROGRAM MS1 (TAPE3)
DIMENSION INDEX (11), DATA (25)
CALL OPENMS (3,INDEX,11,0)

†These routines can be used as functions or subroutines. The value is always returned via the argument and the normal function return.
††Refer to section 5, part 3 for further information.
†††Refer to section 7, part 3 for further information.
CALL READMS (u,fwa,n,k)†

Transmits data from mass storage to central memory. fwa is the central memory address of the first word of the record. n is the number of central memory words transferred. Number index k = 1 ≤ k ≤ lngh - 1. Name index k = any 60-bit quantity except ±0. u is the unit designator.

Example: CALL READMS(3,DATA,25,6)

CALL WRITMS(u,fwa,n,k,r,s)†

Transmits data from central memory to mass storage. u,fwa,n,k are the same as for READMS. r = +1 rewrites in place. Unconditional request; fatal error is printed if new record length exceeds old record length. r = -1 rewrites in place if space is available, otherwise writes at end of information. r = 0 no rewrite; writes normally at end of information. The r parameter can be omitted if the s parameter is omitted. The default value for r is 0 (normal write).

s = 1 writes subindex marker flag in index control word for this record. s = 0 does not write subindex marker flag in index control word for this record. The s parameter can be omitted; its default value is 0.

The s parameter is included for future random file editing routines. Current routines do not test the flag, but the user should include this parameter in new programs, when appropriate, to facilitate transition to a future edit capability.

Example: CALL WRITMS (3,DATA,25,NRKEY)

CALL STINDX (u,ix,lngh,t)†

Changes index in central memory from master to subindex. u,ix,lngh,t are the same as OPENMS.

Example: CALL STINDX (2,SUBIX,10)

CALL CLOSMS (u)†

Writes index from central memory to file and closes file.

Example: CALL CLOSMS (7)

CALL STRACE

Provides subroutine calling traceback information from the subroutine which calls STRACE back to the main program. Traceback information is written to the file DEBUG. To obtain traceback information interspersed with the source program, DEBUG should be equivalence to OUTPUT in the PROGRAM statement. (Refer to section 11, STRACE).

†Refer to section 7, part 3 for further information.
FUNCTIONS

RANF (n)

Random number generator. Returns values uniformly distributed over the range \([0,1]\). \(n\) is a dummy argument which is ignored.

LOCF(a)

Returns address of argument \(a\), which can be any type. Result is type integer.

UNIT (u)

Returns buffer status on unit \(u\). Result is type real. 
-1 Unit ready, no error. 
+0 Unit ready, EOF encountered. 
+1 Unit ready, parity error encountered.

Example: \(\text{IF (UNIT(2))30,40,70}\)

EOF(u)†

Gives input/output status on non-buffer unit. If zero, no end-of-file was encountered on previous read. Result is type real.

Example: \(\text{IFL = EOF (4)}\)

LENGTH(u)†

Gives number of central memory words read on the previous buffer or mass storage input/output request for a designated file. Result is type integer.

Example: \(\text{CMW = LENGTH(5)}\)

IOCHEC(u)†

Gives parity status on non-buffer unit. If zero, no parity error occurred on previous read.

LEGVAR(a)

Checks variable \(a\). Result is -1 if variable is indefinite, +1 if out of range, and 0 if normal. Variable \(a\) is type real; result is type integer.

†Refer to section 5, part 3 for further information.
The following subroutines are included for compatibility with previous processors only and should be avoided by new programs.

**CALL FTNBIN**(i,m,IRAY)

Null routine. All parameters ignored. Exists only for compatibility reasons.

**CALL SLITE**(i)

Turns on sense light i. If i = 0, turn all sense lights off. If i is other than (0-6), an informative diagnostic is printed; and sense lights are not changed.

**CALL SLITET**(i,j)

Tests sense light. If sense light i is on, j = 1, if sense light i is off, j = 2. Always turns sense light i off. If i is other than 1-6, an informative diagnostic is printed; all sense lights remain unchanged; and j = 2.

(Note: Logical variables generally provide a more efficient method of testing a condition than do calls to SLITE or SLITET).

**CALL EXIT**

Terminates program execution and returns control to the operating system.

**CALL WRITEC**(a,b,n)

Transfers data from central memory to extended core storage or LCM.

**CALL READEC**(a,b,n)

Transfers data from extended core storage or LCM to central memory. a is a simple variable or array element located in central memory. b is a simple variable or array element located in an extended core storage block or LCM. n is an integer constant or expression. n consecutive words of data are transferred beginning with a in central memory and b in extended core storage.
Examples:

```fortran
PROGRAM PIE(OUTPUT, TAPE6=OUTPUT)
DATA CIRCLE, DUD/2*0.0/
NAMELIST/OUT/PI

DO 1 I = 1, 10000
   X=RANF(DUD)
   Y=RANF(DUD)
   IF(X*X+Y*Y.LE.1.) CIRCLE=CIRCLE+1.
1 CONTINUE

PI=4.*CIRCLE/10000.
WRITE(6,OUT)

STOP
END

PROGRAM TP (TAPE1, OUTPUT)
INTEGER REC(512), RNUMB
REWIND 1
DO 4 RNUMB = 1, 10000

1 BUFFER IN (1, 1) (REC(1), REC(512))

2 IF (UNIT(1)) 3, 5, 5

3 K=LENGTH(1)

C LENGTH RETURNS THE NUMBER OF WORDS IN CENTRAL MEMORY

4 PRINT 100, RNUMB, (REC(I), I=1, K)

100 FORMAT (7HORECORD, IS/(1X, 10A10))

5 STOP
END
```
PROGRAM LOGIC(INPUT, OUTPUT, TAPE5=INPUT)
LOGICAL MALE, PHD, SINGLE, ACCEPT
INTEGER AGE
PRINT 20
20 FORMAT (*1 LIST OF ELIGIBLE CANDIDATES*)
3 READ (5,1) LNAME, FNAME, MALE, PHD, SINGLE, AGE
1 FORMAT (2A10, 3L5, I2)
IF (EOF(5)) 6
4 ACCEPT = MALE .AND. PHD .AND. SINGLE .AND. (AGE .GT. 25 .AND.
S AGE .LT. 45)
IF (ACCEPT) PRINT 2, LNAME, FNAME, AGE
2 FORMAT (1H0, 2A10, 3X, I2)
GO TO 3
6 STOP
END

PROGRAM LIBS (OUTPUT)
C EXTERNAL DATE
C
CALL DATE (TODAY)
CALL TIME (CLOCK)
PRINT 2, TODAY, CLOCK
2 FORMAT (*1TODAY=*, A10, * CLOCK=*, A10)
C
CALL SECON(TYME)
LOCATN=LOCF(DATE)
CALL RANGE(SEED)
PRINT 3, TYME, LOCATN, LOCATN, SEED, SEED

I-8-16 60305600 A
To input or output data, the following information is required:

Unit number of the input/output device

List of FORTRAN variables to receive input data or from which results are to be output.

Layout or format of data

READ or WRITE statements specify the device and the list. The form of data is designated by the FORMAT statement.

Data can be formatted or unformatted. In formatted mode, display code character strings are converted and transferred according to a FORMAT statement. In unformatted mode, data is transferred in the form in which it normally appears in storage, no conversion takes place, and no FORMAT statement is used.

Input/output control statements are discussed below. Input/output lists and the FORMAT statements are covered in section 10.

The following definitions apply to all input/output statements:

\[ u \]
Input/output unit; the SCOPE operating system associates this unit with an internal file name which may be:

Integer constant of one or two digits (leading zeros are discarded). The compiler associates these numbers with file names of the type TAPEu, where \( u \) is the file designator (refer to PROGRAM statement, section 7).

Simple integer variable name with a value of:

1 - 99, or

A display code file name (L format, left justified with zero fill). This is the internal logical file name.

\[ fn \]
Format designator; a FORMAT statement number or the name of an array containing the format specification. The statement number must identify a FORMAT statement in the program unit containing the input/output statement.

\[ iolist \]
Input/output list specifying items to be transmitted (section 10).
Under the SCOPE operating system, all information is considered to be a file or part of a file. Local to a given job, a file is identified by a logical file name (the internal file named, u). All control card references to a file identify it by the logical file name. The internal central memory representation of a logical file name consists of its literal value in display code, left justified and zero filled.

SCOPE treats several file names as special cases. When one of these names is used, SCOPE makes the following automatic dispositions, unless the user has defined an alternate disposition:

- Card input is assigned to the file INPUT.
- Data in the file OUTPUT is assigned to the printer.
- Data in the file PUNCH is assigned to the card punch as coded card output.
- Data in the file PUNCHB is output on the card punch as binary card output.

**FORTRAN RECORD LENGTH**

Formatted logical records can be a maximum of 150 characters for input, and 137 characters for output. The maximum length formatted logical records for cards is 80 characters.

The length of an unformatted FORTRAN logical record is determined by the length of the input/output list, and can be any size.

**CARRIAGE CONTROL**

In SCOPE output files assigned to the printer, a maximum of 137 characters can be specified for a line, but only 136 characters are printed. The first character of a line is the carriage control; it is never printed. The second character in the line appears in the first print position. The printer control characters are listed in section 10. For off-line printing, printer control is determined by the installation printer routine.

If more than 137 characters are specified for a line, a fatal execution time error results and an error message is printed.

**OUTPUT STATEMENTS**

**PRINT**

```
PRINT fn, iolist
```

This statement transfers information from the storage locations named in the input/output list to the file named OUTPUT, according to the specification in the format designator, fn. If the user has not specified an alternate assignment, the file OUTPUT is sent to the printer.
PROGRAM PRINT (OUTPUT)
A=1.2
B=3HYES
N=19
PRINT 4,A,B,N
FORMAT (G20.6,A10,I5)

The iolist can be omitted. For example.

PRINT 20
20 FORMAT (3OH THIS IS THE END OF THE REPORT)

PUNCH

Data is transferred from the storage locations specified by iolist to the SCOPE file PUNCH. If the user has not specified an alternate assignment, the file PUNCH is output on the standard punch unit as Hollerith codes, 80 characters or less per card in accordance with format specification, fn. If the card image is longer than 80 characters, a second card is punched with the remaining characters.

PROGRAM PUNCH (INPUT,OUTPUT,PUNCH)
READ 3,A,B,C
FORMAT (3G12.6)
ANSWER = A + B - C
IF (A .EQ. 99.99) STOP
PRINT 4, ANSWER
FORMAT (G20.6)
PUNCH 5,A,B,C,ANSWER
FORMAT (3G12.6,G20.6)
GO TO 2
END

The iolist can be omitted. For example.

PUNCH 30
30 FORMAT (10H LAST CARD)
FORMATTED WRITE

```
WRITE (u,fn) iolist
```

Data is transferred from storage locations specified by iolist to the unit u according to FORMAT declaration fn.

```
PROGRAM RITE (OUTPUT,TAPES-OUTPUT)
  X=2.1
  Y=3.
  M=7
  WRITE (6,100) X,Y,M
100 FORMAT (2F6.2,14)
  STOP
END
```

The iolist can be omitted. For example.

```
WRITE (4,27)
27 FORMAT (32H THIS COLUMN REPRESENTS X VALUES)
```

UNFORMATTED WRITE

```
WRITE (u) iolist
```

Example:

```
PROGRAM OUT(OUTPUT,TAPE10-OUTPUT)
  .
  .
  .
  DIMENSION A(260),B(4000)
WRITE (10) A,B
END
```
This statement is used to output binary records. Information is transferred from the list variables, iolist, to the specified output unit, u, with no FORMAT conversion. One record is created by an unformatted WRITE statement. (Refer to section 5, part 3). If the list is omitted, the statement writes a null record on the output device. A null record has no data but contains all other properties of a legitimate record.

**INPUT STATEMENTS**

**FORMATTED READ**

The user should test for an end-of-file after each READ statement to avoid input/output errors. If an attempt is made to read on unit u and an EOF was encountered on the previous read operation on this unit, execution terminates and an error message is printed. (Refer to section 5, part 3, EOF FUNCTION.)

```
7 READ fn,iolist
```

This statement transmits data from the INPUT file to the locations named in iolist. Data is converted in accordance with format specification fn.

```
PROGRAM RLIST(INPUT, OUTPUT)
READ 5,X,Y,Z
5 FORMAT (3G20.2)
RESULT = X-Y+Z
PRINT 100, RESULT
100 FORMAT (10X,G10.2)
STOP
END
```

```
READ (u,fn) iolist
```

```
READ (u,fn)
```

This statement transmits data from unit, u, to storage locations named in iolist according to FORMAT specification fn. The number of words in the list and the FORMAT specifications must conform to the record structure on the input unit. If the list is omitted, READ (u,fn) spaces over one FORTRAN record (section 10, FORTRAN Record /) unless the H specification is used to read Hollerith characters into an existing H field within the format specification.

```
PROGRAM IN (INPUT, OUTPUT, TAPE=INPUT, TAPE=OUTPUT)
READ (4,200) A,B,C
200 FORMAT (3F7.3)
A = B*C-A
WRITE (7,50) A
50 FORMAT (50X,F7.4)
STOP
```

60305600 A
UNFORMATTED READ

READ (u) iolist

READ (u)

One record (refer to section 5, part 3) of information is transmitted from the specified unit, u, to the storage locations named in iolist. Records must be in binary form; no format statement is used. The information is transmitted from the designated file in the form in which it exists on the file. If the number of words in the list exceeds the number of words in the record, excess words in the list retain their previous values. If iolist is omitted READ (u) spaces over one record. If the number of locations specified in the iolist is less than the number of words in the logical record, an execution diagnostic is printed.

```fortran
PROGRAM AREAD (INPUT,OUTPUT,TAPE2=INPUT)
READ (2) X,Y,Z
SUM = X+Y+Z/2.
WRITE (10) SUM
END
```

FILE MANIPULATION STATEMENTS

REWIND u

The REWIND operation positions a file so that the next FORTRAN input/output operation references the first record in the file. A mass storage file is positioned at the beginning of information. If the file is already at beginning of information, the statement acts as a do-nothing statement. (Refer to BACKSPACE/REWIND, section 5, part 3 for further information.)

Example:

REWIND 3

BACKSPACE u

Unit u is backspaced one logical record. If the file is at beginning of information, this statement acts as a do-nothing statement. 7600 only: BACKSPACE is permitted for F, S, or W record format or tape files with one record per block. (Refer to BACKSPACE/REWIND, section 5, part 3 for further information.)
Example:

```
    DO 1 LUN = 1,10,3
       1 BACKSPACE LUN
```

Files TAPE1, TAPE4, TAPE7, and TAPE10 are backspaced one logical record.

```
7    ENDFILE u
```

An end-of-file mark is written on the designated unit.

Example:

```
    IOUT = 6LOUTPUT
       END FILE IOUT
```

End-of-file is written on the file OUTPUT.

Extended core storage and mass storage input/output statements are discussed in section 7, part 3.

**BUFFER STATEMENTS**

The buffer statements and the read/write statements both accomplish data input/output; however, they differ in the following respects:

A buffer control statement initiates data transmission and then returns control to the program so that it can perform other tasks while data transmission is in progress. A read/write statement completes data transmission before returning control to the program.

In a buffer control statement, parity must be specified by a parity indicator. In the read/write control statement, the mode of transmission formatted (display code) or unformatted (binary) is tacitly implied.

The read/write control statements are associated with a list and, if formatted, with a FORMAT statement. The buffer statements are not associated with a list; data is transmitted to or from a block of storage.

```
7    BUFFER IN (u,p) (a,b)
```

$p$ Integer constant or simple integer variable. Designates parity on 7-track magnetic tape. zero designates even parity; one designates odd parity. $p$ is inoperative for other peripheral devices.
First word of record to be transmitted.

Last word of record to be transmitted. The address of b must be greater than the address of a. Arrays are stored in the order in which they appear in the dimension declaration with larger subscripts at higher addresses.

Information is transmitted from unit u in either formatted or unformatted mode to storage locations a through b. Between the time a BUFFER IN statement is executed and the time a UNIT function on the same unit indicates the buffer operation is complete, neither the unit u nor the contents of storage locations a through b must be referenced by any statement. Only one record (section 5, part 3) is read for each BUFFER IN statement. If buffer status is not checked, the result of the last buffer operation is unpredictable.

```
1       5       7
| PROGRAM TP (TAPE1, OUTPUT)
| INTEGER REC(512), RNUMB
| REWIND 1
| DO 4 RNUMB = 1, 10000
1       4
| BUFFER IN (1, 1) (REC(1), REC(512))
2       3
| IF UNIT(I) 3, 5, 5
| K = LENGTH(I)
C LENGTH RETURNS THE NUMBER OF WORDS IN CENTRAL MEMORY
4
| PRINT 100, RNUMB, (REC(I), I = 1, K)
100
| FORMAT (7H0RECORD, I5/(1X, 10A10))
5
| STOP
| END
```

Odd parity information is input from logical unit 1 beginning at the first word of the record REC(1), and extending through the last word of the record REC(512). The IF UNIT statement tests the status of the buffer operation. If the buffer operation is completed without error, statement 3 is executed. If an EOF or a parity error is encountered, control transfers to statement 5 and the program stops.

Additional Example:

```
DIMENSION CALC(50)
BUFFER IN (1, 0) (CALC(1), CALC(50))
```

Even parity information is input from logical unit 1 beginning at the first word of the record, CALC(1), and extending through CALC(50), the last word of the record.
BUFFER OUT (u,p) (a,b)

u,p,a,b are the same as for BUFFER IN

Contents of storage locations a through b are written on unit u in even or odd parity.

Examples:

```
BUFFER OUT(2,0)(OUTBUF(1),OUTBUF(4))
DIMENSION ALPHA(100)
BUFFER OUT (2,1)(ALPHA(1),ALPHA(100))
```

One record is written for each BUFFER OUT statement. Section 5, part 3 contains further information regarding BUFFER IN/OUT statements.

**NAMELIST**

The NAMELIST statement permits input and output of groups of variables and arrays with an identifying name. No format specification is used.

```
NAMELIST/group name_1 /a_1 ,...,a_n/ .../group name_n /a_1 ,...,a_n
```

group name Symbolic name which must be enclosed in slashes and must be unique within the program unit.

a_1,...,a_n List of variables, array elements, or array names separated by commas.

The NAMELIST group name identifies the succeeding list of variables or array names. Whenever an input or output statement references the NAMELIST name, the complete list of associated variables or array names is read or written.

A NAMELIST group name must be declared in a NAMELIST statement before it is used in an input/output statement. The group name may be declared only once, and it may not be used for any purpose other than a NAMELIST name in the program unit. It may appear in any of the input/output statements in place of the format number:

```
READ (u, group name)
READ group name
WRITE (u, group name)
PRINT group name
PUNCH group name
```
It may not, however, be used in an ENCODE or DECODE statement in place of the format number. When a NAMELIST group name is used, the list must be omitted from the input/output statement.

A variable, array element or array name may belong to one or more NAMELIST groups.

Data read by a single NAMELIST name READ statement must contain only names listed in the referenced NAMELIST group. A set of data items may consist of any subset of the variable names in the NAMELIST. The value of variables not included in the subset remain unchanged. Variables need not be in the order in which they appear in the defining NAMELIST statement.

```
PROGRAM NMLIST (INPUT,OUTPUT,TAPLE5=INPUT,TAPLE6=OUTPUT)
NAMELIST/SHIP/A,B,C,I1,I2
READ(5,SHIP)
IF (A.GT.0.0) STOP
A=B*C
I1=I2 + 11
WRITE (6,SHIP)
END
```

Input record

```
SHIP A=12.2,B=20.,C=3.4,I1=8,I2=50$
```

Output

```
$SHIP
A = 0.234E+02,
B = 0.2E+02,
C = 0.34E+01,
I1 = 58,
I2 = 50,
$END
```

When a READ statement references a NAMELIST group name, input data, in the format described below, is read from the designated unit, u. If no group name is found, and an end of file is encountered, a fatal error occurs.
INPUT DATA

Data items succeeding $ NAMELIST group name are read until another $ is encountered.

Blanks must not appear:
- Between $ and NAMELIST group name
- Within array names and variable names
- Within constants and repeated constant fields

Blanks may be used freely elsewhere.

A maximum of 150 characters per input record is allowed. More than one record may be used in input data. The first column of each record is ignored. All except the last record must end with a constant followed by a comma.

Data items separated by commas may be in three forms:
- variable = constant
- array name = constant, constant
- array name(integer constant subscripts) = constant, constant

Constants can be preceded by a repetition factor and an asterisk.

Example:

$5^3(1.7,-2.4)$ five complex constants.

Constants may be integer, real, double precision, complex or logical. Logical constants must be of the form: .TRUE., .T., .FALSE., .F. or F. A logical variable may be replaced only by a logical constant. A complex variable may be replaced only by a complex constant. A complex constant must have the form (real constant, real constant). Any other variable may be replaced by an integer, real or double precision constant; the constant is converted to the type of the variable.
OUTPUT

```
7
| WRITE(u, group name)
```

All variables and arrays, and their values, in the list associated with the NAMELIST group name are output on the designated unit, u. They are output in the order of specification in the NAMELIST Statement. Output consists of at least three records. The first record is a $ in column 2 followed by the group name; the last record is a $ in column 2 followed by the characters END.

Example:

```
PROGRAM NAME(INPUT, OUTPUT, TAPE5=INPUT, TAPE6=OUTPUT)
NAMELIST/VALUES/TOTAL, QUANT, COST
DATA QUANT, COST/15, 3.02/
TOTAL = QUANT*COST*1.3
WRITE (6, VALUES)
STOP
END
```

Output

```
$VALUES
TOTAL = 0.5888999999999E+02,
QUANT = 0.15E+02,
COST = 0.302E+01,
$END
```

No data appears in column 1 of any record. If the logical unit referenced is the standard punch unit and a variable crosses column 80, this and following variables are punched on the next card. The maximum length of a record written by a WRITE (u, group name) statement is 130 characters. Logical constants appear as T or F. Elements of an array are output in the order in which they are stored.

Records output by a WRITE (u, group name) statement may be read by a READ (u, group name) statement using the same NAMELIST name.

Example:

```
NAMELIST/ITEMS/X, Y, Z
.
.
.
WRITE (6, ITEMS)
```
Output record:

$ITEMS
X=734.2,
Y=2374.9,
Z=22.25,
$END

This output may be read later in the same program using the following statement:

READ(5,ITEMS)

ARRAYS IN NAMELIST

In input data the number of constants, including repetitions, given for an array name should not exceed the number of elements in the array.

Example:

DIMENSION BAT(10)
NAMELIST/HAT/BAT,DOT
READ (5,HAT)

$HAT
BAT=2,3,8*4,DOT=1.05$END

The value of DOT becomes 1.05, the array BAT is as follows:

BAT(1) 2
BAT(2) 3
BAT(3) 4
BAT(4) 4
BAT(5) 4
BAT(6) 4
BAT(7) 4
BAT(8) 4
BAT(9) 4
BAT(10) 4

Example:

DIMENSION GAY(5)
NAMELIST/DAY/GAY,BAY,RAY
READ (5,DAY)

Input Record:

$DAY
GAY(3)=7.2,GAY(5)=3.0,BAY=2.3,RAY=77.2$END

array element (integer constant subscript) = constant....constant
When data is input in this form, the constants are stored consecutively beginning with the location given by the array element. The number of constants need not equal, but may not exceed, the remaining number of elements in the array.

Example:

```
DIMENSION ALPHA (6)
NAMELIST/BETA/ALPHA,DELTA,X,Y
READ (5,BETA)
```

Input record:

```
2
$BETA ALPHA(3)=7.,8.,9.,DELTA-2.$
```

In storage

```
ALPHA(3) 7.
ALPHA(4) 8.
ALPHA(5) 9.
DELTA 2.
```

Data initialized by the DATA statement can be changed later in the program by the NAMELIST statement.

Example:

```
PROGRAM COSTS (INPUT,OUTPUT,TAPE5=INPUT,TAPE6=OUTPUT)
DATA TAX,INT,ACCUM,ANET/23.,10,500.2,17.0/
NAMELIST/RECORDS/TAX,INT,ACCUM,ANET
FIRST = TAX + INT
SECOND = FIRST * SUM
.
.
READ(5, RECORDS)
.
.
```

Input Record:

```
2
$RECORDS TAX=27., ACCUM=666.2$
```

Example:

```
DIMENSION Y(3,5)
LOGICAL L
COMPLEX Z
NAMELIST/HURRY/I1,I2,I3,K,M,Y,Z,L
READ (5,HURRY)
```
Input Record:

\$HURRY I1=1,L=.TRUE.,I2=2,I3=3.5,Y(3,5)=26,Y(1,1)=11, 
12.0E1,13,4*14,Z=(1..2.),K=16,M=17\$

produce the following values:

\[
\begin{align*}
I1=1 & \quad Y(1,2)=14.0 \\
I2=2 & \quad Y(2,2)=14.0 \\
I3=3 & \quad Y(3,2)=14.0 \\
Y(3,5)=26.0 & \quad Y(1,3)=14.0 \\
Y(1,1)=11.0 & \quad K=16 \\
Y(2,1)=120.0 & \quad M=17 \\
Y(3,1)=13.0 & \quad Z=(1..2.) \\
& \quad L=.TRUE.
\end{align*}
\]

**ENCODE AND DECODE**

The ENCODE and DECODE statements are used to reformat data in memory; information is transferred under FORMAT specifications from one area of central memory (small core) storage to another.

ENCODE is similar to a WRITE statement, and DECODE is similar to a READ statement. Data is transmitted under format specifications, but ENCODE and DECODE transfer data internally; no peripheral equipment is involved. For example, data can be converted to a different format internally without the necessity of writing it out on tape and rereading under another format.

**ENCODE**

\[
\begin{align*}
&\text{ENCODE (c,fn,v) iolist} \\
\end{align*}
\]

v Variable or array name which supplies the starting location of the record to be encoded.

c Unsigned integer constant or simple integer variable specifying the length of each record.

The first record starts with the leftmost character of the location specified by v and continues for c characters, 10 characters per computer word. If c is not a multiple of 10, the record ends before the end of the word is reached; and the remainder of the word is blank filled. Each new record begins with a new computer word. c must be less than or equal to 150.

fn Format designator, statement label or integer variable, which must not be a NAME- LIST group name.

iolist List of variables to be transmitted to the location specified by v.
Example:

```
PROGRAM ENCODE (OUTPUT)
DIMENSION A(2),ALPHA(4)
DATA A,B,C/10HABCDDEFHIJ,10HKLMNOPQRSTUVWXYZ,7H123456/
ENCODE (40,1,ALPHA)A,B,C
1 FORMAT (2A4,A5,A6)
PRINT 2,ALPHA
2 FORMAT (20H1CONTENTS OF ALPHA =,8A10)
STOP
END
```

In memory after ENCODE statement has been executed.

<table>
<thead>
<tr>
<th>ALPHA (1)</th>
<th>ALPHA (2)</th>
<th>ALPHA (3)</th>
<th>ALPHA (4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABCDKLNMUV</td>
<td>WXYZ12345</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ENCODE is a core-to-core transfer of data, which is similar to WRITE. Only data in central memory or small core can be transferred by the ENCODE statement. Data in the io list in internal form is converted under FORMAT specifications, fn. and written in display code into an array or variable.

An integral number of words is allocated for each record created by an ENCODE statement. If c is not a multiple of 10, the record ends before the end of the word is reached; and the remainder of the word is blank filled.

The number of characters allocated for any single record in the encoded area must not exceed 150.

Example:

```
10 FORMAT (16F10.4) illegal (length > 150 characters); fatal error and the message EXCEEDED RECORD SIZE is printed.
```

```
10 FORMAT (10F10.4/6F10.4) legal
```

If the list and the format specification transmit more than the number of characters specified per record, an execution error message is printed. If the number of characters transmitted is less than the length specified by c, remaining characters in the record are blank filled.

For example, in the following program which is similar to program ENCODE above, the format statement has been changed; so that two records are generated by the ENCODE statement. A(1) and A(2) are written with the format specification 2A4, the / indicates a new record, and the remaining portion of the 40 character record, c, is blank filled. B and C are written into the second record with the specification A5 and A6, and the remaining characters are blank filled. The dimensions of the array ALPHA must be increased to 8 to accommodate two 40-character records.
5

PROGRAM TWO (OUTPUT)
DIMENSION A(2), ALPHA(8)
DATA A*B*C/10HABCDUEFGHIJ10HKLMNOPQRSTUVWXYZ1234567
ENCODE (401*ALPHA)A*B*C
FFORMAT (CA4/A5*A6)
PRINT 2*ALPHA
FFORMAT (20H1CONTENTS OF ALPHA =*BA10)
STOP
END

Output:

CONTENTS OF ALPHA = ABCDKLMN

UVWXYZ12345

If this same ENCODE statement is altered to:

ENCOD (33,1,ALPHA)A,B,C
1 FORMAT (2A4/A5,A6)

The contents of ALPHA remain the same. When a record ends in the middle of a word the remainder of the word is blank filled (each new record starts at the beginning of a word).

<table>
<thead>
<tr>
<th>Record 1</th>
<th>Record 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABCDKLMN</td>
<td>blank fill</td>
</tr>
<tr>
<td>ALPHA(1)</td>
<td>blank fill</td>
</tr>
<tr>
<td>ALPHA(2)</td>
<td>UVWXYZ1234</td>
</tr>
<tr>
<td>ALPHA(3)</td>
<td>5</td>
</tr>
<tr>
<td>ALPHA(4)</td>
<td>blank fill</td>
</tr>
<tr>
<td>ALPHA(5)</td>
<td>end of record</td>
</tr>
<tr>
<td>ALPHA(6)</td>
<td>end of record</td>
</tr>
<tr>
<td>ALPHA(7)</td>
<td>blank fill</td>
</tr>
<tr>
<td>ALPHA(8)</td>
<td>end of record</td>
</tr>
</tbody>
</table>

The array in core must be large enough to contain the total number of characters specified in the ENCODE statement. For example, if 70 characters are generated by the ENCODE statement, the array starting at location v (if v is a single word element) must be dimensioned at least 7. If 27 characters are generated, the array must be dimensioned 3. If only 6 characters are generated, v can be a 1-word variable.

The following example illustrates that it is possible to encode an area into itself, and the information previously contained in the area will be destroyed.

517

PROGRAM ENCO2 (OUTPUT)
1=10HBCDEFGHIJK
1A=1H1
ENCOD (B*10*I) I*1A*1
10 FORMAT (A3*A1*R4)
PRINT I1*1
11 FORMAT (A11)
END

Printout is:

BCD1HIJKbb
ENCODE may be used to calculate a field definition in a FORMAT specification at object time. Assume that in the statement FORMAT (2A10,1m) the programmer wishes to specify m at some point in the program. The following program permits m to vary in the range 2 through 9.

```plaintext
IF(M.LT.10.AND.M.GT.1)1,2
 1 ENCODE (10,100,SPECMAT)M
100 FORMAT (7H(2A10,I,11,1H))
  .
  .
  .
PRINT SPECMAT,A,B,J
```

M is tested to ensure it is within limits; if it is not, control goes to statement 2, which could be an error routine. If M is within limits, ENCODE packs the integer value of M with the characters (2A10,I ). This packed FORMAT is stored in SPECMAT. SPECMAT contains (2A10,1m).

A and B will be printed under specification A10, and the quantity J under specification I2, through I9 according to the value of m.

The following program is another example of forming FORMAT statements internally:

```plaintext
PROGRAM IGEN (OUTPUT,TAPE6-OUTPUT)
  DO 9 J=1,50
  ENCODE (10,7,FMT)J
  7 FORMAT (2H(I,I2,1H))
  9 WRITE (6,FMT)J
  STOP
END
```

In memory, FMT is first (I 1) then (I 2), then (I 3), etc.

DECODE

```
7
```

```plaintext
DECODE (c,fn,v) iolist
```

c, fn. and v are the same as for ENCODE.

iolist is the list to receive variables from the location specified by v. iolist conforms to the syntax of an input/output list.
PROGRAM ADD (INPUT,OUTPUT,TAPES=INPUT,TAPE6=OUTPUT)
DIMENSION CARD (8), INK (77)
2 READ (5,100) KEY1, CARD
100 FORMAT (11,7A10,A9)
   IF (EOF (5)) 80,90
90 IF (KEY1-2) 3,8,3
   CALL ERROR1
   GO TO 2
   WRITE (6,300) CARD
300 FORMAT (1H1,7A10,A7///)
   DECODE (77,17,CARD) INK
17 FORMAT (7711)
   ITOT = 0
   DO 4 I = 1,77
4   ITOT = ITOT + INK(I)
   ISAVE = ITOT
   WRITE (6,200) ISAVE
200 FORMAT (19X,*TOTAL OF 77 SCORES ON CARD = *,110)
80 STOP
END
SUBROUTINE ERROR1
WRITE (6,1)
1 FORMAT (5X,*NUMBER IS NOT 2*)
   RETURN
END

(An explanation of this program appears in part 2).

DECODE is a core-to-core transfer of data similar to READ. Only data in central memory or small core can be transferred by the DECODE statement. Display code characters in a variable or an array, v, are converted under format specifications and stored in the list variables, iolst. DECODE reads from a string of display code characters in an array or variable in central memory or small core; whereas the READ statement reads from an input device. Both statements convert data according to the format specification, fn. Using DECODE, however, the same information can be read several times with different DECODE and FORMAT statements.

Starting at the named location, v, data is transmitted according to the specified format and stored in the list variables. If the number of characters per record is not a multiple of 10 (a display code word contains 10 display code characters) the balance of the word is ignored. However, if the number of characters specified by the list and the format specification exceeds the number of characters per record, an execution error message is printed. If DECODE attempts to process an illegal display code character, or a character illegal under a given specification, that character is treated as a blank and conversion continues. Under the SCOPE operating system, a binary zero byte in the low order bits of a word is used to terminate a unit record. If DECODE encounters a zero character (6 bits of binary zeros), other than at the end of a line, the character is interpreted as a colon and conversion continues.

Example:

\[
c ≠ \text{multiple of 10}
\]

```
DECODE (16,1,GAMMA) X,B,C,D
1 FORMAT (2A8)
```
Data transmitted under this DECODE specification would appear in storage as follows:

\[
\begin{align*}
x &= \text{HEADER 1} \\
y &= \text{HEADER 1} \\
z &= \text{HEADER 1} \\
w &= \text{HEADER 1} \\
x &= \text{HEADER 1} \\
y &= \text{HEADER 1} \\
z &= \text{HEADER 1} \\
w &= \text{HEADER 1} \\
\end{align*}
\]

The following illustrates one method of packing the partial contents of two words into one. Information is stored in core as:

\[
\begin{align*}
\text{LOC(1)} &= \text{SSSSSSSSSS} \\
\text{LOC(2)} &= \text{SSSSSSSSSS} \\
\text{LOC(3)} &= \text{SSSSSSSSSS} \\
\text{LOC(4)} &= \text{SSSSSSSSSS} \\
\text{LOC(5)} &= \text{SSSSSSSSSS} \\
\text{LOC(6)} &= \text{DDDDDDDDDD} \\
\end{align*}
\]

To form SSSSSDDDDDD in storage location NAME:

\[
\begin{align*}
\text{DECODE}(10, 1, \text{LOC}(6)) &\rightarrow \text{TEMP} \\
1 &\text{FORMAT}(5X, A5) \\
\text{ENCODE}(10, 2, \text{NAME}) &\rightarrow \text{LOC}(1), \text{TEMP} \\
2 &\text{FORMAT}(2A5) \\
\end{align*}
\]

The DECODE statement places the last 5 display code characters of LOC(6) into the first 5 characters of TEMP. The ENCODE statement packs the first 5 characters of LOC(1) and TEMP into NAME.

Using the R specification, the example above could be shortened to:

\[
\begin{align*}
\text{ENCODE}(1C, 1, \text{NAME}) &\rightarrow \text{LOC}(1), \text{LOC}(6) \\
1 &\text{FORMAT}(A5, R5) \\
\end{align*}
\]
This chapter covers input/output lists and FORMAT statements. Input/output statements, which include READ and WRITE, are covered in section 9.

**INPUT/OUTPUT LISTS**

The list portion of an input/output statement specifies the items to be read or written and the order of transmission. The input/output list can contain any number of elements. List items are read or written sequentially from left to right. Their order must correspond to the FORMAT specification associated with the list, and they must be separated by commas.

If no list appears on input, a record is skipped. Only Hollerith information from the FORMAT statement can be output with a null (empty) output list.

A list consists of a variable name, an array name, an array element name, or an implied DO list. On output, the data list can include Hollerith constants and arithmetic expressions.

Multiple lists may appear, separated by commas, each of which may be enclosed in parentheses, such as: (...),(...).

An array name without subscripts in an input/output list specifies the entire array in the order in which it is stored. The entire array (not just the first word of the array) is read or written.

Subscripts in an input/output list may be any valid subscript (section 2).

**Examples:**

```
READ 100,A,B,C,D
READ 200,A,B,C(I),D(3,4),E(I,J,7),H
READ 101,J,A(J),I,B(I,J)
READ 202,DELT
READ 102, DELTA(5*J+2,5*I-3,5*K),C,D(I+7)
READ 3,A,(B,C,D),(X,Y)
```

An implied DO list is a list followed by a comma and an implied DO specification, all enclosed in parentheses.
A DO-implied specification takes one of the following forms:

\[ i = m_1, m_2, m_3 \quad \quad \quad i = m_1, m_2 \]

The elements \( i, m_1, m_2, \) and \( m_3 \) have the same meaning as in the DO statement. The range of a DO-implied specification is that of the DO-implied list. The values of \( i, m_1, m_2, \) and \( m_3 \) must not be changed within the range of the DO implied list by a READ statement.

On input or output, the list is scanned and each variable in the list is paired with the field specification provided by the FORMAT statement. After one item has been input or output, the next format specification is taken together with the next element of the list, and so on until the end of the list.

Example:

\[
\text{READ (5,20) L,M,N} \\
20 \text{ FORMAT (I3,I2,I7)}
\]

Input record

\[
100\text{234567812}
\]

100 is read into the variable L under the specification I3, 22 is read into M under the specification I2, and 3456712 is read into N under specification I7.

**ARRAY TRANSMISSION**

Input/output of array elements may be accomplished by using an implied DO loop. The list of variables followed by the DO loop index, is enclosed in parentheses to form a single element of the input/output list.

Example:

\[
\text{READ (5,100) (A(I),I-1,3)}
\]

has the same effect as the statement

\[
\text{READ (5,100) A(1),A(2),A(3)}
\]

The general form for an implied DO loop is:

\[
(\ldots(L\text{ist},i=m_1,m_2,m_3),i_2=j_1,j_2,j_3),\ldots,i_n,k_1,k_2,k_3)\]

\(m, j, k\) are unsigned integer constants or predefined positive integer variables. If \( m, j, \) or \( k \) is omitted, a one is used for incrementing.

\(i_1,\ldots, i_n\) are index variables. An index variable should not be used twice in the same implied DO nest, but array names, array elements and variables may appear more than once.
The first index variable \( i \) defined in the list is incremented first. \( i \) is set equal to \( m \) and the associated list is transmitted; then \( i \) is incremented by \( m \), until \( m \) is exceeded. When the first index variable reaches \( m \), it is reset to \( m \); the next index variable at the right (\( l \)) is incremented; and the process is repeated until the last index variable \( (i_n) \) has been incremented, until \( k \) is exceeded.

The general form for an array is:

\[
((A(I, J, K), i=1,m, i_1=1,m_1), i_2=1,n_2, n_3), i_3=1,k, k_3)
\]

Example:

```
READ 100,((A(JV,JX),JV=2,20,2),JX=1,30)
READ 200,(BETA(3*JON+7),JON=JONA,JONB,JONC)
READ 300,(((ITMLIST(I,J-1,K-2),I=1,25),J=2,N),K=IVAR,IVMAX,4)
```

An implied DO loop can be used to transmit a simple variable more than one time. For example, the list item \( (A(K),K=1,5) \) causes the variable \( B \) to be transmitted five times. An input list of the form \( K,(A(I),I=1,K) \) is permitted, and the input value of \( K \) is used in the implied DO loop. The index variable in an implied DO list must be an integer variable.

Examples of simple implied DO loop list items:

```
READ 400,(A(I),I=1,10)
400 FORMAT (I20.10)
```

The following DO loop would have the same effect:

```
DO 5 I=1,10
  5 READ 400, A(I)
```

Example:

CAT, DOG, and RAT will be transmitted 10 times each with the following iolist

\[
(CAT, DOG, RAT, I=1,10)
\]

Implied DO loops may be nested.

Example:

```
DIMENSION MATRIX(3,4,7)
READ 100, MATRIX
100 FORMAT (I6)
```

Equivalent to the following:

```
DIMENSION MATRIX(3,4,7)
READ 100,((MATRIX(I,J,K),I=1,5),J=1,4),K=1,7)
```
The list is similar to the nest of DO loops:

```
DO 5 K=1,7
DO 5 J=1,4
DO 5 I=1,3
5 READ 100, MATRIX(I,J,K)
```

Example:

The following list item transmits nine elements into the array E in the order: E(1,1), E(1,2), E(1,3), E(2,1), E(2,2), E(2,3), E(3,1), E(3,2), E(3,3)

```
READ 100, ((E(I,J), J=1,3)I=1,3)
```

Example:

```
READ 100, (((((A(I,J,K), B(I,L)C(J,N), I=1,10), J=1,5),
X K=1,8), L=1,15), N=2,7)
```

Data is transmitted in the following sequence:

```
A(1,1,1), B(1,1), C(1,2), A(2,1,1), B(2,1), C(1,2)
...A(10,1,1), B(10,1), C(1,2), A(1,2,1), B(1,1), C(2,2)
...A(10,2,1), B(10,1), C(2,2), ...A(10,5,1), B(10,1), C(5,2)
...A(10,5,8), B(10,1), C(5,2), ...A(10,5,8), B(10,15), C(5,2)
```

Data can be read from or written into part of an array by using the implied DO loop.

Examples:

```
READ (5,100) (MATRIX(I), I=1,10)
100 FORMAT (F7.2)
```

Data (consisting of one constant per record) is read into the first 10 elements of the array MATRIX. The following statements would have the same effect:

```
DO 40 I = 1,10
40 READ (5,100) MATRIX(I)
100 FORMAT (F7.2)
```

In this example, the statements are equivalent: numbers are read, one from each card, into the elements $\text{MATRIX}(1)$ through $\text{MATRIX}(10)$ of the array $\text{MATRIX}$. In the second case, however, the READ statement is encountered each time the DO loop is executed; and a new card is read for each element of the array. Each execution of a READ statement reads at least one record regardless of the FORMAT statement.
READ (5,100) (MATRIX(I),I=1,10)
100 FORMAT (F7.2)

In the above statements, the implied DO statement is part of the READ statement; therefore, the FORMAT statement specifies the format of the data input and determines when a new card will be read.

If statement 100 FORMAT (F7.2) had been 100 FORMAT (4F20.10), only three cards would be read.

To read data into an entire array, it is necessary only to name the array in a list without any subscripts.

Example:

DIMENSION B (10,15)
READ 13,B

is equivalent to

READ 13 ((B(I,J),I=1,10),J=1,15)

The entire array B will be transmitted in both cases.

**FORMAT STATEMENT**

Input and output can be formatted or unformatted. Formatted information consists of strings of characters acceptable to the FORTRAN processor. Unformatted information consists of strings of binary word values in the form in which they normally appear in storage. A FORMAT statement is required to transmit formatted information.

```
  5 7
```

| sn | FORMAT (f_{s_1}, \ldots, f_{s_n}) |

- sn Statement label which must appear
- \( f_{s_1}, \ldots, f_{s_n} \) Set of one or more field specifications separated by commas and/or slashes and optionally grouped by parentheses

Example:

```
READ (5,100) INK,NAME,AREA
100 FORMAT (10X,I4,I2,F7.2)
```

FORMAT is a non-executable statement which specifies the format of data to be moved between input/output device and central memory or small core. It is used in conjunction with read and write statements, and it may appear anywhere in the program.
The FORMAT specification is enclosed in parentheses. Blanks are not significant except in Hollerith field specifications.

Each item in an input/output list is associated with a corresponding field specification in a FORMAT statement. The FORMAT statement specifies the external format of the data, and the type of conversion to be used, and defines the length of the FORTRAN record or records.

The type of conversion should correspond to the type of the variable in the input/output list. The FORMAT statement specifies the type of conversion for the input data, with no regard to the type of the variable which receives the value when reading is complete.

For example:

```
INTEGER N
READ (5,100) N
100 FORMAT (F10.2)
```

A floating point number is assigned to the variable N which could cause unpredictable results if N is referenced later as an integer.

**DATA CONVERSION**

The following types of data conversion are available:

- **srEw.d** Single precision floating point with exponent
- **srFw.d** Single precision floating point without exponent
- **srGw.d** Single precision floating point with or without exponent
- **srDw.d** Double precision floating point with exponent
- **rIw** Decimal integer conversion
- **rLw** Logical conversion
- **rAw** Alphanumeric conversion
- **rRw** Alphanumeric conversion
- **rOw** Octal integer conversion

E,F,G,D,I,L,A,R, and O are the conversion codes which indicate the type of conversion.

- **w** Non-zero, unsigned, integer constant which specifies the field width in number of character positions in the external record. This width includes any leading blanks, + or - signs, decimal point, and exponent.
- **d** Integer constant which represents the number of digits to the right of the decimal point within the field. On output all numbers are rounded.
- **r** Unsigned integer constant which indicates the conversion code is to be repeated.
- **s** Optional; it represents a scale factor.
The field width \( w \) must be specified for all conversion codes. If \( d \) is not specified for \( w.d \), it is assumed to be \( zero \). \( w \) must be \( \geq d \).

**FIELD SEPARATORS**

Field separators are used to separate specifications and groups of specifications. The format field separators are the slash (/) and the comma. The slash is also used to specify demarcation of formatted records.

**CONVERSION SPECIFICATION**

Leading blanks are not significant in numeric input conversions; other blanks are treated as zeros. Plus signs may be omitted. An all blank field is considered to be minus zero, except for logical input, where an all blank field is considered to be \( FALSE \). When an all blank field is read with a Hollerith input specification, each blank character will be translated into a display code 55 octal.

For the \( E, F, G \), and \( D \) input conversions, a decimal point in the input field overrides the decimal point specification of the field descriptor.

The output field is right justified for all output conversions. If the number of characters produced by the conversion is less than the field width, leading blanks are inserted in the output field. The number of characters produced by an output conversion must not be greater than the field width. If the field width is exceeded, an asterisk is inserted in the leading position of the field.

Complex data items are converted on input/output as two independent floating point quantities. The format specification uses two single precision conversion elements.

Example:

```plaintext
COMPLEX A,B,C,D
PRINT 10,A
10 FORMAT (F7.2,E8.2)
READ 11,B,C,D
11 FORMAT (2E10.3,2(F8.3,F4.1))
```

Data of differing types may be read by the same FORMAT statement. For example:

```plaintext
10 FORMAT (15,F15.2)
```

specifies two numbers, the first of type integer, the second of type real.

```plaintext
READ (5,15) NO,NONE,INK,A,B,R
15 FORMAT (3I5,2F7.2,A4)
```

reads 3 integer variables

reads 2 real variables

reads 1 alphanumeric variable
**Iw INPUT**

The I conversion is used to input decimal integer constants.

w

w is a decimal integer constant designating the total number of characters in the field including signs and blanks.

The plus sign may be omitted for positive integers. When a sign appears, it must precede the first digit in the field. Blanks are interpreted as zeros. An all blank field is considered to be minus zero. Decimal points are not permitted. The value is stored in the specified variable. Any character other than a decimal digit, blank, or the leading plus or minus sign in an integer field on input will terminate execution.

Example:

```
READ 10,I,J,K,L,M,N
10 FORMAT (I3,I7,12,I5,I2,I4)
```

**Input Card:**

```
139bb-15bb18bb7bb1bb4
```

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>7</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**In storage:**

I contains 139
J contains -1500
K contains 18
L contains 7
M contains -0
N contains 104

**Iw OUTPUT**

The I specification is used to output decimal integer values.

w

w is a decimal integer constant designating the total number of characters in the field including signs and blanks. If the integer is positive the plus sign is suppressed. Only numbers in the range of $-2^{w+1}$ to $2^w - 1$ are output correctly; even though, internally, integers outside this range can be generated. If the absolute value of the integer is greater than $2^{w+1}$ ($2^{w+1} = 281 474 976 710 655$), an X is printed in the field.

The specification Iw outputs a number in the following format:

```
ba...a
```

b Minus sign if the number is negative, or blank if the number is positive

a...a May be a maximum of 15 digits
The output quantity is right justified with blanks on the left. If the field is too short, characters are stored from the right, and an asterisk occupies the leftmost position.

Example:

```
PRINT 10,I,J,K
10 FORMAT (I9,I10,I5)

I contains -3762
J contains +4762937
K contains +13

Result: 8 10 5
          \ bbb=3762bbb4762937bbb13

1st blank taken as printer control character
```

Example:

```
WRITE (6,100)N,M,I
100 FORMAT (I5,I6,I9)

N contains +20
M contains -731450
I contains +205

Result: 4 6 9
         \ bb20 31450bbb205

1st blank taken as printer control character
 specification too small * indicates most significant digits missing
```

Ew.d OUTPUT

E specifies conversion between an internal real value and an external number written with exponent.

Ew.d

w is an unsigned integer designating the total number of characters in the field. w must be wide enough to contain digits, plus or minus signs, decimal point, E, the exponent and blanks. Generally, w \geq d + 6 for negative numbers and w \geq d + 5 for positive numbers. Positive numbers need not reserve a space for the sign of the number. If the field is not wide enough to contain the output value, an asterisk is inserted in the leftmost position of the field. If the field is longer than the output value, the quantity is right justified with blanks on the left. If the value being converted is indefinite, an I is printed in the field; if it is out of range, an R is printed.

d specifies the number of digits to the right of the decimal within the field. If d is zero or blank, the decimal point and digits to the right of the decimal do not appear.
The specification Ew.d produces output in the following format:

\[ b \cdot a \pm eee \]
\[ \text{or} \]
\[ b \cdot aE \pm ee \]

-308 \leq eee \leq 337

- 0 \leq ee \leq 99

b

Minus sign if the number is negative, or blank if the number is positive

a...a

Most significant digits

eee

Digits in the exponent

Examples:

```
PRINT 10,A
10 FORMAT (E10.3)
```

Result:

\[-.673E+02 \text{ or } b.673E+02\]

```
PRINT 10,A
10 FORMAT (E13.3)
```

Result:

\[bbb-.673E+02 \text{ or } bbbb.673E+02\]

```
PRINT 10,A
10 FORMAT (1H,E8.3)
```

Result:

\[*.67E+02\]

```
PRINT 10,A
10 FORMAT (1H,E10.6)
```

Result:

\[*.6732E+02\]

If an integer variable is output under the Ew.d specification, results are unpredictable since the internal format of real and integer values differ. An integer value does not have an exponent and will be printed, therefore, as a very small value or 0.0.
**Ew.d** INPUT

E specifies conversion between an external number written with an exponent and an internal real value.

**Ew.d**

w is an unsigned integer designating the total number of characters in the field, including plus or minus signs, digits, decimal point, E and exponent. If an external decimal point is not provided, d acts as a negative power-of-10 scaling factor. The internal representation of the input quantity is:

\[(\text{integer subfield}) \times 10^d \times 10 \text{ (exponent subfield)}\]

For example, if the specification is E10.8, the input quantity 3267E+05 is converted and stored as: $3267 \times 10^5 \times 10^8 = 3.267$.

If an external decimal point is provided, it overrides d. If d does not appear it is assumed to be zero.

In the input data, leading blanks are not significant; other blanks are interpreted as zeros.

An input field consisting entirely of blanks is interpreted as minus zero.

The following diagram illustrates the structure of the input field:

```
  +    +    
  -    -    
 digit D
```

The integer subfield begins with a + or - sign, a digit, or a blank; and it may contain a string of digits. The integer field is terminated by a decimal point, E, +, - or the end of the input field.

The fraction subfield begins with a decimal point and terminates with an E, +, - or the end of the input field. It may contain a string of digits.

The exponent subfield may begin with E, + or -. When it begins with E, the + is optional between E and the string of digits in the subfield.

For example, the following are valid equivalent forms for the exponent 3:

\[E+03, \ E \ 03,E03,E+3, E3, +3, +3,E +3\]

The value of the string of digits in the exponent subfield must be less than 323.
Valid subfield combinations:

+1.6327E-04  Integer-fraction-exponent
-32.7216      integer-fraction
+ 328 + 5     integer-exponent
.629E-1       fraction-exponent
+136          integer only
136           integer only
.07628431     fraction only
E-06 (interpreted as zero) exponent only

If the field length specified by w in Ew.d is not the same as the length of the field containing the input number, incorrect numbers may be read, converted, and stored. The following example illustrates a situation where numbers are read incorrectly, converted and stored; yet there is no immediate indication that an error has occurred:

READ 20,A,B,C
20 FORMAT (E9.3,E7.2,E10.3)

On the card, input quantities are in three adjacent fields, columns 1-24:

\[
\begin{array}{ccc}
-6.47E-01 & -2.36 & 5.321E+02 \\
& 9 & 5 & 10 \\
-6.47E-01 & & \\
+6.47E-01 & -2.36 & 5 \\
+6.47E-01 & -2.36 & 5 & 321E+02bb
\end{array}
\]

First, +647E-01 is read, converted and placed in location A. The second specification E7.2 exceeds the width of the second field by two characters. The number -2.36 + 5 is read instead of -2.36. The specification error (E7.2 instead of E5.2) caused the two extra characters to be read. The number read (-2.36 + 5) is a legitimate input number. Since the second specification incorrectly took two digits from the third number, the specification for the third number is now incorrect. The number .321E+02bb is read. Trailing blanks are treated as zeros; therefore the number .321E+0200 is read converted and placed in location C. Here again, this is a legitimate input number which is converted and stored, even though it is not the number desired.
Examples of Ew.d input specifications:

<table>
<thead>
<tr>

</tbody>
</table>

FW.d OUTPUT

The F specification outputs a real number without a decimal exponent.

FW.d

w is an unsigned integer which designates the total number of characters in the field including the sign (if negative) and decimal point. N must be ≥ d + 2.

d specifies the number of places to the right of the decimal point. If d is zero or omitted, the decimal point and digits to the right do not appear.

If the number is positive, the plus sign is suppressed. If the field is too short, one asterisk appears in the leftmost position of the output field. If the field is longer than required, the number is right justified with blanks on the left. If the value being converted is indefinite, an I is printed in the field; if it is out of range, an R is printed.

60306900 A
The specification Fw.d outputs a number in the following format:

```
+32.694
```

b...ala...a

b Minus sign if the number is negative, or blank if the number is positive.

Examples:

<table>
<thead>
<tr>
<th>Value of A</th>
<th>FORMAT Statement</th>
<th>PRINT Statement</th>
<th>Printed Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>+32.694</td>
<td>10 FORMAT (1H,F6.3)</td>
<td>PRINT 10,A</td>
<td>32.694</td>

<tr>
<td>+32.694</td>
<td>11 FORMAT (1H,F10.3)</td>
<td>PRINT 11,A</td>
<td>bbbbb32.694</td>
</tr>
<tr>
<td>-32.694</td>
<td>12 FORMAT (1H,F6.3)</td>
<td>PRINT 12,A</td>
<td>*2.694</td>
</tr>
<tr>
<td>.32694</td>
<td>13 FORMAT (1H,F4.3,F6.3)</td>
<td>PRINT 13,A,A</td>
<td>.327bb.327</td>
</tr>
</tbody>
</table>

The specification 1H is the carriage control character.

**Fw.d INPUT**

On input F specification is treated identically to the E specification.

Examples of the F format specification:

<table>
<thead>
<tr>
<th>Input Field</th>
<th>Specification</th>
<th>Converted Value</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>367.2593</td>
<td>F8.4</td>

<td>F5.2</td>
<td>-0.00</td>
<td>Blanks in input field interpreted as -0</td>
</tr>
</tbody>
</table>
Gw.d INPUT

Input under control of G specification is the same as for the E specification. The rules which apply to the E specification apply to the G specification.

Gw.d

w  Unsigned integer which designates the total number of characters in the field including E, digits, sign, and decimal point

d  Number of places to the right of the decimal point

Example:

    READ (5,11) A,B,C
    11 FORMAT (G15.6,2G12.4)

Gw.d OUTPUT

Output under control of the G specification is dependent on the size of the floating point number being converted. The number is output under the F conversion unless the magnitude of the data exceeds the range which permits effective use of the F. In this case, it is output under E conversion with an exponent.

Gw.d

w  Unsigned integer which designates the total number of characters in the field including digits, signs and decimal point, the exponent E, and any leading blanks.

  d  Number of significant digits output.

If a number is output under the G specification without an exponent, four spaces are inserted to the right of the field (these spaces are reserved for the exponent field E±00). Therefore, for output under G conversion w must be greater than or equal to d + 6. The six extra spaces are required for sign and decimal point plus four spaces for the exponent field.

Example:

    PRINT 200,YES
    200 FORMAT (G10.3)
    YES contains 77.132

    Output:  b77.1bbbb
              b denotes a blank

If the decimal point is not within the first d significant digits of the number, the exponential form is used (G is treated as if it were E).
Example:

```
PRINT 100, EXIT
100 FORMAT (G10.3)
```

Output: \(0.1215E+07\)

Example:

```
READ (5,50) SAMPLE
  .
  .
  .
WRITE (6,20) SAMPLE
20 FORMAT (1X,G17.8)
```

<table>
<thead>
<tr>
<th>Data read by READ statement</th>

<td>F conversion</td>
</tr>
</tbody>
</table>

Dw.d OUTPUT

Dw.d

Type D conversion is used to output double precision variables. D conversion corresponds to E conversion except that D replaces E at the beginning of the exponent subfield. If the value being converted is indefinite, an I is printed in the field; if it is out of range, an R is printed.
Examples of type D output:

```plaintext
DOUBLE A,B,C
A = 111111.1111
B = 222222.2222
C = A + B
PRINT 10,A,B,C
10 FORMAT (3D23.10)
```

```
.1111111111D+06  .2222222222D+06  .3333333333D+06
```

The specification Dw.d produces output in the following format:

```
b a...a ± eee  -308 ≤ eee ≤ 337
b a...a D ± eee  0 ≤ ee ≤ 99
```

- **b** Minus sign if the number is negative, or blank if the number is positive.
- **a...a** Most significant digits.
- **ee** Digits in the exponent.

**Dw.d INPUT**

D conversion corresponds to E conversion except that D replaces E at the beginning of the exponent subfield.

**Ow INPUT**

Octal values are converted under the O specification.

**Ow**

w is an unsigned integer designating the total number of characters in the field. The input field may contain a maximum of 20 octal digits. Blanks are allowed and a plus or minus sign may precede the first octal digit. Blanks are interpreted as zeros and an all blank field is interpreted as minus zero. A decimal point is not allowed.

The list item corresponding to the Ow specification should be integer.
Example:

```
INTEGER P, Q, R
READ 10, P, Q, R
10 FORMAT (010, 012, 02)
```

Input Card:

```
3737373737 6666644444 0
```

Input storage (octal representation):

```
P 00000000003737373737
Q 000000066606644444
R 7777777777777777
```

**Ow OUTPUT**

The Ow specification is used to output octal integer values, the internal representation of the number.

**Ow**

w is an unsigned integer designating the total number of characters in the field. If w is less than 20, the rightmost digits are output. For example, if the contents of location P were output with the following statement, the digit 3737 would be output.

```
WRITE (6, 1) P
100 FORMAT (1X, Ow)
```

If w is greater than 20, the 20 octal digits (20 octal digits = a 60-bit word) are right justified with blanks on the left.

For example, if the contents of location P are output with the following statement:

```
WRITE (6, 200) P
200 FORMAT (1X, Ow)
```

Output would appear as follows:

```
b00000000003737373737
```

A negative number is output in one's complement internal form.
Example:

```
I = -11
WRITE (5,200) I
```

Output would appear as follows:

```
bb7777777777777764
```

The specification Ow produces output in the following format:

```
a...a
```

```
a...a      octal digits
```

**Aw INPUT**

The A specification is used to input alphanumeric characters.

**Aw**

w is an unsigned integer designating the total number of characters in the field.

Alphanumeric information is stored as 6-bit display code characters, 10 characters per 60-bit word. For example, the digit 4 when read under A specification is stored as a display code 37. If w is less than 10, the input quantity is stored left justified in the word; the remainder of the word is filled with blanks.

Example:

```
READ (5,100) A
100 FORMAT (A7)
```

Input record:

```
EXAMPLE
```

When EXAMPLE is read it is stored left justified in the 10 character word

```
1234567890
```

If w is greater than 10, the rightmost 10 characters are stored and remaining characters are ignored.

Example:

```
READ (5,200) B
200 FORMAT (A13)
```

60306900 A I-10-19
Input record:

```
1  13
SPECIFICATION
```

In storage:

```
12345678910
SPECIFICATION
```

`READ (5,10) Q,P,R`

```
10 FORMAT (A10,A10,A5)
```

Input record:

```
THIS IS AN EXAMPLE I KNOW
```

In storage:

```
12345678910
Q THIS IS AN
P EXAMPLE I
R EXAM
```

**Aw OUTPUT**

The A specification is used to output alphanumeric characters.

**Aw**

w is an unsigned integer designating the total number of characters in the field. If w is less than 10, the leftmost characters in the word are printed. For example, if the contents of location A in the Aw input example are output with the following statements:

```
WRITE (6,300)A
300 FORMAT (1X,A4)
```

In storage:

```
A  EXAMPLE I
```

Characters EXAM are output
If \( w \) is greater than 10, the value is right justified in the output field with blanks on the left. For example, if \( A \) in the previous example is output with the following statements:

```
WRITE (6,400) A
400 FORMAT (1X,A12)
```

Printed output appears as follows:

```
bbEXAMPLEbb  \( b = \text{blank} \)
```

**Rw INPUT**

\( w \) is an unsigned integer designating the total number of characters in the field. The R specification is the same as the A specification with the following exception. If \( w \) is less than 10, the input characters are stored right justified, with binary zero fill on the left.

Example:

```
READ (5,600) H00,RAY
600 FORMAT (R10,R5)
```

Input card:

```
RESULTS OF TEST

10 5
```

In storage:

```
H00 RESULTS\000
RAY 0000\000\000
```

```
b = \text{blank} \n```

**Rw OUTPUT**

**Rw**

\( w \) is an unsigned integer designating the total number of characters in the field.

This specification is the same as the A specification with the following exception. If \( w \) is less than 10, the rightmost characters are output. For example, if RAY from the previous example is output with the following statements:

```
WRITE (6,700) RAY
700 FORMAT (1X,R3)
```

Characters EST are output.
**Lw INPUT**

The L specification is used to input logical variables.

\[
\text{Lw}
\]

\( w \) is an unsigned integer designating the total number of characters in the field.

If the first non-blank character in the field is T, the logical value .TRUE. is stored in the corresponding list item which should be of type logical. If the first non-blank character is F, the value .FALSE. is stored. If the first non-blank character is not T or F, a diagnostic is printed. An all blank field has the value .FALSE.

**Lw OUTPUT**

\[
\text{Lw}
\]

\( w \) is an unsigned integer designating the total number of characters in the field.

Variables output under the L specification should be of type logical. A value of .TRUE. or .FALSE. in storage is output as a right justified T or F with blanks on the left.

Example:

\[
\begin{align*}
\text{LOGICAL I, J, K} \\
\text{PRINT 5, I, J, K} \\
5 \text{ FORMAT (3L3)}
\end{align*}
\]

Output:

\[b\, T\, b\, F\, b\, T\]

**SCALE FACTORS**

The scale factor P is used to change the position of a decimal point of a real number when it is input or output. Scale factors may precede D, E, F and G format specifications.

\[
\begin{align*}
nP & Dw.d \\
nP & Ew.d \\
nP & Fw.d \\
nP & Gw.d \\
nP
\end{align*}
\]

\( n \) is the scale factor. It is a positive (unsigned) or negative (signed) integer constant. \( w \) is an unsigned integer constant designating the total width of the field. \( d \) determines the number of digits to the right of the decimal point.
A scale factor of zero is established when each format control statement is first referenced; it holds for all F, E, G, and D field descriptors until another scale factor is encountered.

Once a scale factor is specified, it holds for all D, E, F, and G specifications in that FORMAT statement until another scale factor is encountered. To nullify this effect for subsequent D, E, F, and G specifications, a zero scale factor, 0P must precede a specification.

Example:

\[ 15 \text{ FORMAT}(2\text{PE14.3,FI0.2,GI6.2,OP4F13.2}) \]

The 2P scale factor applies to the E14.3 format specification and also to the F10.2 and G16.2 format specification. The 0P scale factor restores normal scaling \((10^0 = 1)\) for the subsequent specification 4F13.2.

A scaling factor may appear independently of a D, E, F or G specification. It holds for all subsequent D, E, F or G specifications within the same FORMAT statement, until changed by another scaling factor.

Example:

\[ \text{FORMAT}(3P,5X,\text{E12.6,FI0.3,OPD18.7,-1P,F5.2}) \]

E12.6 and F10.3 specifications are scaled by \(10^5\), the D18.7 specification is not scaled, and the F5.2 specification is scaled by \(10^1\).

The specification \((3P,3I9,F10.2)\) is the same as the specification \((3P3I9,3PF10.2)\).

**Fw.d SCALING**

**INPUT**

The number in the input field is divided by \(10^0\) and stored. For example, if the input quantity 314.1592 is read under the specification 2PF8.4, the internal number is \(314.1592 \times 10^2 = 3.141592\).

**OUTPUT**

The number in the output field is the internal number multiplied by \(10^0\). In the output representation, the decimal point is fixed; the number moves to the left or right, depending on whether the scale factor is plus or minus. For example, the internal number 3.1415926536 may be represented on output under scaled F specifications as follows:

<table>
<thead>
<tr>
<th>Specification</th>
<th>Output Representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>F13.6</td>
<td>3.141593</td>
</tr>
<tr>
<td>1PF13.6</td>
<td>31.415927</td>
</tr>
<tr>
<td>3PF13.6</td>
<td>3141.592654</td>
</tr>
<tr>
<td>-1PF13.6</td>
<td>.314159</td>
</tr>
<tr>
<td>-3PF13.6</td>
<td>.003142</td>
</tr>
</tbody>
</table>
Ew.d SCALING

Ew.d scaling on input is the same as Fw.d scaling on input.

OUTPUT

The scale factor has the effect of shifting the output number left n places while reducing the exponent by n. Using 3.1415926536, the following are output representations corresponding to scaled E specifications:

<table>
<thead>
<tr>

Gw.d SCALING

INPUT

Gw.d scaling on input is the same as Fw.d scaling on input.

OUTPUT

The effect of the scale factor is suspended unless the magnitude of the data to be converted is outside the range that permits the effective use of F conversion.

X

The X specification is used to skip characters in an input line and insert blank characters in an output line. It is not associated with a variable in the input/output list.

nX

n

Number of characters to be skipped or the number of blanks to be inserted on output, n blanks are inserted in an output record.

0X is ignored. bX is interpreted as 1X. The comma following X in the specification list is optional.
Example:

```
WRITE (6,100) A,B,C
100 FORMAT (F9.4,4X,F7.5,4X,I3)
```

Output record:

```
-342.743bbbbb1.53190bbbbb22 b is a blank on input n columns are skipped.
```

Example:

```
READ 11,R,S,T
11 FORMAT (F5.2, 3X, F5.2, 6X, F5.2)
```

or

```
11 FORMAT (F5.2, 3XF5.2, 6XF5.2)
```

Input card:

```
14.62bb$13.78bcOSTb15.97
```

In storage:

```
R  14.62
S  13.78
T  15.97
```

Example:

```
INTEGER A
PRINT 10,A,B,C
10 FORMAT (I2,6X,F6.2,6X,E12.5)
```

Result:

```
7bbbbbbbb13.60bbbbbb.146237E+04
```

**nH OUTPUT**

The H specification is used to output strings of alphanumeric characters and like X, H is not associated with a variable in the input/output list.
\( nH \)

\( n \)  
Number of characters in the string including blanks. \( n \) may not exceed 136 characters.

\( H \)  
Denotes a Hollerith field. The comma following the \( H \) specification is optional.

For example, the statement:

\[
\text{WRITE (6,1)} \\
1 \text{ FORMAT (15HbENDbOFbPROGRAM)}
\]

can be used to output the following on the output listing.

\text{END OF PROGRAM}

Examples:

Source program:

\[
\text{PRINT 20} \\
20 \text{ FORMAT (28HbBLANKbCOUNTbINbANbHbFIELD.)}
\]

produces output record:

\text{BLANKbCOUNTbINbANbHbFIELD.}

Source program:

\[
\text{PRINT 30,A} \\
30 \text{ FORMAT (6HbLMAX=,F5.2)}
\]

produces output record:

\text{LMAX=1.50}

\( nH \) INPUT

The \( H \) specification can be used to read Hollerith characters into an existing \( H \) field within the FORMAT statement.

Example:

Source program:

\[
\text{READ 10} \\
10 \text{ FORMAT (27Hbbbbbbbbbbbbbbbbbbbbbbb)}
\]
Input card:

After READ, the FORMAT statement labeled 10 contains the alphanumeric information read from the input card; a subsequent reference to statement 10 in an output statement acts as follows:

PRINT 10

produces the print line:

Character strings delimited by a pair of * or \# symbols can be used as alternate forms of the H specification, and can appear anywhere the H form of the Hollerith constant can appear. The paired symbols delineate the Hollerith field. This specification need not be separated from other specifications by commas. If the Hollerith field is empty, or invalidly delimited a fatal execution error occurs, and an error message is printed.

An asterisk cannot be output using the specification * *. For example,

PRINT 1 1 FORMAT ("ABC*DE")

The second * in the FORMAT statement causes the specification to be interpreted as *ABC* and DE*, which is not valid.

The H specification or \#...\# could be used to output this correctly:

PRINT 1 1 FORMAT (7H ABC*DE)

Output appears as follows: ABC*DE

PRINT 2 2 FORMAT (\# ABC*DE\#)

Output appears as follows: ABC*DE

\# can be represented within \#...\# by two consecutive \# symbols.

Example:

PRINT 3 3 FORMAT (\# DON\#T\#)
Output examples:

```
PRINT 10
10 FORMAT (* SUBTOTALS*)
```

produces the following output:

```
SUBTOTALS
```

```
WRITE (6,20)
20 FORMAT ('RESULT OF CALCULATIONS IS AS Follows')
```

produces the following output:

```
RESULT OF CALCULATIONS IS AS Follows
```

```
PRINT 1, SQRT!, SQRT(4.)
1 FORMAT (A10,E10.2)
```

produces the following output:

```
SQRT 2.0
```

Note: ! is output as ' on some printers.

The "..." specification can be used to read alphanumeric characters into an existing "..." field within the FORMAT statement. Characters are stored in the heading until either an asterisk is encountered in the input field or all the spaces in the format specification are filled. For example, if the format specification contains 10 spaces and the 6th character in the input field is an asterisk, all the characters to the left of the asterisk are stored in the heading; and the remaining character positions in the heading are filled with blanks.

Input examples:

Source program:

```
READ 10
10 FORMAT (*bbbbbbbbbbbaa staring"
```

Input card:

```
DFORTRAN FOR THE 6600
```

A subsequent reference to statement 10 in an output control statement:

```
PRINT 10 produces:
```

```
FORTRAN FOR THE 6600
```

I-10-28

60306900 A
Source program:

```fortran
READ 10
10 FORMAT ('bbbbbbbb')
```

Input card:

```
9HEAD
```

PRINT 10 produces:

```
HEABB
```

```fortran
READ (5,600)
600 FORMAT ('bbbbbbbbbbbb')  b is a blank
```

Input record:

```
MAGNITUDE CALCULATION
```

WRITE (6,600) produces:

```
MAGNITUDE C
```

**FORTRAN RECORD /**

The slash indicates the end of a FORTRAN record anywhere in the FORMAT specification list. Where a / is used a comma is not required, but it is allowed, to separate field specification elements. Consecutive slashes may appear in a list and need not be separated from other list elements by commas. During output, the slash indicates the end of a record. During input, it specifies further data comes from the next record.

Example:

```fortran
PRINT 10
10 FORMAT (6X, 7HEADING//3X, 5INPUT, 8H OUTPUT)
```

Printout:

```
HEADING ____________ line 1
    (blank) _______ line 2
    (blank) _______ line 3
INPUT OUTPUT ____________ line 4
```

Each line corresponds to a formatted record. The second and third records are blank and produce the line spacing illustrated.
A repetition factor can be used to indicate multiple slashes.

\[ n(/) \]

\[ n \quad \text{Unsigned integer indicating the number of slashes required.} \quad n - 1 \quad \text{lines are skipped on output.} \]

Example:

\[
\text{PRINT 15, (A(I),I=1,9)} \\
15 \text{ FORMAT (8HbRESULTS4(/),(3F8.2))}
\]

Format statement 15 is equivalent to:

\[ 15 \text{ FORMAT (8HbRESULTS///, (3F8.2))} \]

Printout:

\[
\begin{array}{cccc}
\text{RESULTS} & \text{blank} & \text{line 1} \\
\text{blank} & \text{line 2} \\
\text{blank} & \text{line 3} \\
3.62 & -4.03 & -9.78 & \text{line 4} \\
-6.33 & 7.12 & 3.49 & \text{line 5} \\
6.21 & -6.74 & -1.18 & \text{line 6} \\
\end{array}
\]

Example:

\[
\text{DIMENSION B(3)} \\
\text{READ (5,100)1A,B} \\
100 \text{ FORMAT (15/3E7.2)}
\]

These statements read two records, the first containing an integer number, and the second containing three real numbers.

\[
\text{PRINT 11,A,B,C,D} \\
11 \text{ FORMAT (2E10.2/2F7.3)}
\]

In storage:

\[
\begin{align*}
A & = -11.6 \\
B & = .325 \\
C & = 46.327 \\
D & = -14.261 \\
\end{align*}
\]

Printout:

\[
\begin{array}{cccc}
b & -1.2E-02 & \text{bbb.33E+00} \\
46.327 & -14.261
\end{array}
\]
PRINT 11,A,B,C,D
11 FORMAT (2E10.2//2F7.3)

Printout:

\[ b=\text{.12E+02 bbb.33E+00} \] line 1

(\text{blank}) line 2

\[ 46.327-14.261 \] line 3

REPEATED FORMAT SPECIFICATION

FORMAT specifications may be repeated by preceding the control characters D,E,F,G,I,A,R,L or O by an unsigned integer giving the number of repetitions required.

100 FORMAT (3I4,2E7.3) is equivalent to: 100 FORMAT (I4,I4,I4,E7.3,E7.3)

50 FORMAT (4G12.6) is equivalent to: 50 FORMAT (G12.6,G12.6,G12.6,G12.6)

A group of specifications may be repeated by enclosing the group in parentheses and preceding it with the repetition factor.

1 FORMAT (I3,2(E15.3,F6.1,2I4))

is equivalent to the following specification if the number of items in the input/output list do not exceed the format conversion codes:

1 FORMAT (I3,E15.3,F6.1,I4,I4,E15.3,F6.1,I4,I4)

Two levels of parentheses, in addition to the parentheses required by the FORMAT statement, are the maximum allowed when groups of specifications are repeated. The following example illustrates maximum nesting of parentheses:

10 FORMAT(1HO,3E10.3/(I2,2(F12.4,F10.3))/D28.17)

If the number of items in the input/output list are fewer than the number of format codes in the FORMAT statement, excess FORMAT codes are ignored.

If the number of items in the input/output list exceed the format conversion codes, when the final right parenthesis in the FORMAT statement is reached, the line formed internally is output. The FORMAT control then scans to the left looking for a right parenthesis within the FORMAT statement. If none is found the scan stops when it reaches the beginning of the FORMAT specification. If, however, a right parenthesis is found, the scan continues to the left until it reaches the field separator which precedes the left parenthesis pairing this right parenthesis. Output resumes with the FORMAT control moving right until either the output list is exhausted or the final right parenthesis of the FORMAT statement is encountered.
Example:

```
300 FORMAT (I3,2(I4,F7.3),I7)
```

is equivalent to storing data in I with format I3, J with I4, E with F7.3, K with I4, F with F7.3, L with I7. Then a new record is read; data is stored in M with the format I4, G with F7.3, N with I4 and R with F7.3.

```
READ (5,100) NEXT, DAY, KAT, WAY, NAT, RAY, MAT
100 FORMAT (I7, (F12.7, I3))
```

NEXT is input with format I7, DAY is input with F12.7, KAT is input with I3. The FORMAT statement is exhausted, (the right parenthesis has been reached) a new card is read, and the statement is rescanned from the group (F12.7, I3). WAY is input with the format F12.7, NAT with I3, RAY with F12.7, MAT with I3.

**PRINTER CONTROL CHARACTER**

The first character of a printer output record is used for carriage control and is not printed. It appears in all other forms of output as data.

The printer control characters are as follows:

<table>
<thead>
<tr>
<th>Character</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blank</td>
<td>Space vertically one line then print</td>
</tr>
<tr>
<td>0</td>
<td>Space vertically two lines then print</td>
</tr>
<tr>
<td>1</td>
<td>Eject to the first line of the next page before printing</td>
</tr>
<tr>
<td>+</td>
<td>No advance before printing; allows overprinting</td>
</tr>
<tr>
<td>Any other character</td>
<td>Refer to the SCOPE Reference Manual</td>
</tr>
</tbody>
</table>

For output directed to the card punch or any device other than the line printer, control characters are not required. If carriage control characters are transmitted to the card punch, they are punched in column one.

Carriage control characters can be generated by any means; however, the H specification is frequently used.

Example:

```
FORMAT (1H0, F7.3, I2, G12.6)
```

```
FORMAT (1H1, I5, 'RESULT = ', F8.4)
```
The "..." specification can be used:

```
FORMAT (1X,14,2F7.3)
```

The blank printer control character can be transmitted by the X specification.

Example:

```
FORMAT (1X,I4,G16.8)
```

Carriage control characters are required at the beginning of every record to be printed, including new records introduced by means of a slash.

Example:

```
PROGRAM LOGIC(INPUT,OUTPUT,TAPE5=INPUT)
LOGICAL MALE,PHD,SINGLE,ACCEPT
INTEGER AGE
PRINT 20
20 FORMAT (*1 LIST OF ELIGIBLE CANDIDATES*)
3 READ (5,1) LNAME,FNAME,MALE,PHD,SINGLE,AGE
1 FORMAT (2A10,3L5,I2)
IF (EOF(5))6,4
4 ACCEPT = MALE .AND. PHD .AND. SINGLE .AND. (AGE .GT. 25 .AND. 
   AGE .LT. 45)
   IF (ACCEPT) PRINT 2,LNAME,FNAME,AGE
2 FORMAT (1H0,2A10,3X,I2)
   GO TO 3
6 STOP
END
```

```
LIST OF ELIGIBLE CANDIDATES

JOHN S. SLIGHT 26
JUSTIN BROWN 30
```
\textbf{Tn}

This specification is a column selection control.

\textbf{Tn}

\begin{itemize}
\item[] \texttt{n} \quad \text{Unsigned integer} \leq 136 \text{ for input/output and} \leq 150 \text{ for ENCODE/DECODE. If } n = \text{zero, column 1 is assumed. }
\end{itemize}

When \texttt{Tn} is used, control skips columns until column \texttt{n} is reached, then the next format specification is processed. Using card input, if \texttt{n} > 80 the column pointer is moved to column \texttt{n}, but a succeeding specification would read only blanks.

\begin{verbatim}
WRITE (31,10)
10 FORMAT (T20, 'LABELS')
\end{verbatim}

The first 19 characters of the output record are skipped and the next six characters, \texttt{LABELS}, are written on output unit number 31 beginning in character position 20.

\begin{verbatim}
READ (20,40)
40 FORMAT (T10, 'COLUMN1')
\end{verbatim}

The first nine characters of the input record are skipped and the next seven, \texttt{COLUMN1}, are read from input tile 20.

With \texttt{T} specification, the order of a list need not be the same as the printed page or card input, and the same information can be read more than once.
Example:

```
5 7
1 PROGRAM TEST (OUTPUT)
  FORMAT (12(10H0123456789))
  PRINT 1
  PRINT 60
   FORMAT (T80,*COMMENTS*,T60,*HEADING4*,T40,
            *HEADING3*,T20,*HEADING2*,T2,*HEADING1*)
  PRINT 10
  FORMAT ('T20X*THIS IS THE END OF THIS RUN*T52*...HONEST*)
  PRINT 1
  STOP
  END
```

Since the first character in a line output to the printer is used for printer control, T2 is output in the first print position.

Example:

The following example shows that it is possible to destroy a previously formed field inadvertently. The specification T5 destroys part of the Hollerith specification 10H DISASTERS.

```
  1 FORMAT (10H DISASTERS,T5,3H123)
  PRINT 1
```

produces the following output:

```
DIS123ERS
```
EXECUTION TIME FORMAT STATEMENTS

Variable FORMAT statements can be read in as part of the data at execution time and used by READ, WRITE, statements later in the program. The format is read in as alphanumeric text under the A specification and stored in an array or a simple variable, or it may be included in a DATA statement. The format must consist of a list of format specifications enclosed in parentheses, but without the word FORMAT or the statement label.

For example, a data card could consist of the characters:

(E7.2,G20.5,F7.4,I3)

The name of the array containing the specifications is used in place of the FORMAT statement number in the associated input/output statement. The array name, which appears with or without subscripts, specifies the location or the first word of the FORMAT information.

For example, assume the following FORMAT specifications:

This information on an input card can be read by the statements of the program such as:

DIMENSION IVAR(3)
READ 1, IVAR
1 FORMAT (3A10)

The elements of the input card are placed in storage as follows:

IVAR(1) (E12.2,F8.
IVAR(2) 2,I7,2E20.
IVAR(3) 3,F9.3,I4)

A subsequent output statement in the same program can refer to these FORMAT specifications as:

PRINT IVAR,A, B, I, C, D, E, J

Produces exactly the same result as the program.

PRINT 10, A, B, I, C, D, E, J
The FORTRAN Extended compiler is called from the library and executed by an FTN control card. The FTN control card calls the compiler, specifies the files to be used for input and output, and indicates the type of output to be produced. This control card may be in any of the following forms:

```
  1
  FTN (p_1, p_2, ..., p_n) comments
```

```
  1
  FTN. comments
```

```
  1
  FTN, p_1, ..., p_n, comments
```

Example:

```
  FTN (A, LRN, G, S=0)
```

The optional parameters, p_1,...,p_n, may be in any order within the parentheses. All parameters, with the exception of the list control options, must be separated by commas. If no parameters are specified, FTN is followed by a period or right parenthesis. If a parameter list is specified, it must conform to the control statement syntax for job control statements as defined in the SCOPE Reference Manual. Card columns following the right parenthesis, or period, can be used for comments; they are ignored by the compiler, but are printed on the dayfile.

```
(p_{1}, ..., p_{n})
```

Default options are used for omitted parameters. Default options are set when the system is installed; but since installations can change default values, the user should consult his installation for possible changes.

In the following description of the FTN control card parameters: Ifn is a 1-7 alphanumeric file name. The first letter must be alphabetic.

The first improperly formed parameter terminates the FTN control card scan. When an error is detected, a dayfile entry is made. A ten character segment of the control card is printed with an asterisk positioned beneath the approximate column in which the error occurred.

* POINTS TO FTN CONTROL CARD ERROR
Example:

Dayfile

22.14.11 FTN(I-TEST,PL-ABC,L-LIST)
22.14.12 (T,PL-ABC,L)
22.14.12 *
22.14.13 * POINTS TO FTN CONTROL CARD ERROR

The job proceeds with the option already processed or terminates and branches to an EXIT(S) card, depending upon the installation option.

I  SOURCE INPUT PARAMETER

I = lfn

Ifn is the name of the file containing the source input. If I=INPUT is specified, source input is on the file INPUT. If I only is specified, source input is on the file COMPILE. If source input is on a file other than INPUT, the I=Ifn form must be used. Compilation stops when an end-of-record (end of section) or end-of-file (end of partition) is encountered.

B  BINARY OBJECT FILE

B

Generated binary object code is output on file LGO.

B = lfn

Generated binary object code is output on file Ifn.

B = 0

No binary object file is produced.

G = lfn

Binary object file is loaded and executed at end of compilation

BG = lfn

GB = lfn

G

I  LIST CONTROL

y = lfn

The list control options specify the type of listing of the source program,y, and the file name, lfn, on which list output is to be written. If no list control options are specified, a listing is produced of the source program with informative and fatal diagnostics. If no file name is specified, OUTPUT is assumed.

y is any combination of one to four list control options selected from the letters: L,O,R,X,N. The letters must not be separated by commas. X and N cannot be specified at the same time.
Lf\text{n} is the file on which output is to be written.

\begin{itemize}
\item \texttt{L=Lf\text{n}} \quad \text{Source program, diagnostics, and short reference map listed (same as omitting list control parameter).}
\item \texttt{L} \quad \text{L defaults to L=OUTPUT.}
\item \texttt{L=0} or \texttt{LR=0} \quad \text{Fatal diagnostics and the statements which caused them are listed. All other output, including intermixed COMPASS, is suppressed.}
\item \texttt{L=0,R=1} \quad \text{Level 1 reference map, fatal diagnostics and the statements which caused them listed. All other output is suppressed.}
\item \texttt{L=0,R=2} \quad \text{Level 2 reference map, fatal diagnostics and the statements which caused them listed. All other output is suppressed.}
\item \texttt{L=0,R=3} \quad \text{Level 3 reference map, fatal diagnostics and the statements which caused them listed. All other output is suppressed.}
\item \texttt{O=Lf\text{n}} \quad \text{Generated object code is listed. The O option must not be used if the E option is selected.}
\item \texttt{R=Lf\text{n}} \quad \text{Symbolic reference map is listed. R is included in the list control options for compatibility reasons only. Refer to R option in this section, and section 14 for full description of reference map.}
\item \texttt{X=Lf\text{n}} \quad \text{A warning diagnostic is given for any non-ANSI usage. For example, if this option is selected and a 7- character symbolic name is used, (legal in FORTRAN Extended, but not defined under ANSI) the following warning diagnostic is printed:}
\begin{center}
7 CHARACTER SYMBOLIC NAME IS NON-ANSI
\end{center}
\item \texttt{N=Lf\text{n}} \quad \text{Listing of informative diagnostics is suppressed; only diagnostics fatal to execution are listed.}
\end{itemize}

For example, LR\text{RON} = \text{Lf\text{n}} specifies all options except non-ANSI diagnostics are to be listed for the file \text{Lf\text{n}}, and \text{L0} selects source program and generated object code listing on OUTPUT.

\section*{E \quad EDITING PARAMETER}

\texttt{E} or \texttt{E=Lf\text{n}}

Compiler generated object code is output as COMPASS card images for the SCOPE maintenance program \texttt{UPDATE} (refer to SCOPE Reference Manual). If \texttt{E} is omitted, normal binary object file is produced. The \texttt{O} and \texttt{C} options must not be specified if the \texttt{E} option is selected.
The object code output file starts with the card image: *DECK, name and ends with the card image: *END
(name is the name of a program unit).

The object code output file Ifn or COMPS is rewound and ready as UPDATE input. No binary file is
produced. COMPASS is not called automatically. When the COMPS file is assembled S=FTNMAC must
be specified on the COMPASS control card.

T ERROR TRACEBACK

This option is provided to assist in debugging programs.

T

Calls to library functions are made with call-by-name sequence (section 10, part 3). Maximum error checking takes place, and full error traceback occurs if an error is detected.

T omitted

The more efficient (but less informative) call-by-value linkages are generated. Minimum error checking takes place, and no traceback is provided if an error is detected. A significant saving in memory space and execution time is realized.

Selecting the D parameter or OPT=0 automatically selects T.

ROUNDED ARITHMETIC SWITCH

( Default: arithmetic not rounded)

ROUND=op

op is an arithmetic operator: + - * / Single precision (real and complex) floating point arithmetic operations are performed using the hardware rounding features (refer to 6000 series and 7600 Computer Systems Reference Manuals). Any combination of the arithmetic operators can be specified. For example: ROUND = + - /

If this parameter is omitted (default condition), arithmetic computations are not rounded.

D DEBUGGING MODE PARAMETER

D or D=Ifn

If the debug facility described in section 12 is used, D or D=Ifn must be specified. This parameter automatically selects fast compilation (OPT=0) and full error traceback (T option). When the debug parameter is selected, any optimization level other than OPT=0 is ignored. A minimum field length of 61000 should be specified on the SCOPE control card if this option is selected.

Ifn is the name of the file on which the user debug deck resides (figure 13-4, section 13). The default option for D=Ifn is D=INPUT.

FTN(D) is equivalent to FTN(D=INPUT,OPT=0,T)
A EXIT PARAMETER

A Compilation terminates and branches to an EXIT(S) control card if fatal errors occur during compilation. If there is no EXIT(S) control card, the job terminates.

Note: The S, GT and SYSEDIT parameters are of interest primarily to system programmers.

S SYSTEM TEXT FILE

S=ln Source of systems text information for intermixed COMPASS assemblies is on file ln.

If the only GT parameter is GT=0, the overlay named SYSTEXT is loaded. If parameter is omitted, information is on SYSTEXT overlay.

S=0 When COMPASS is called to assemble any intermixed COMPASS programs, it will not read in a system text file.

S=ovlname The system text overlay, ovlname, is loaded from the job’s current library set.

S=libname/ ovlname The system text overlay, ovlname, is loaded from the library, libname. Libname can be a user library file or a system library.

GT GET SYSTEM TEXT FILE

GT=ln Loads the first system text overlay, if any, in the sequential binary file, ln.

GT=ln/ ovname Searches the sequential binary file, ln, for a system text overlay with name ovname, and loads the first such overlay encountered.

GT=0 or omitted No system text is loaded from a sequential binary file.

A maximum of seven system texts can be specified. (Any combination of the GT, S and C parameters must not specify more than seven system texts.)

SYSEDIT SYSTEM EDITING

This option is used mainly for system resident programs.

SYSEDIT All input/output references are accomplished indirectly through a table search at object time. File names are not entry points in main program, and subprograms do not produce external references to the file name.
V SMALL BUFFERS OPTION

When this option is selected, the compiler uses 513-word buffers for its intermediate files. Programs with a large number of specifications are compiled with a smaller field length under this option. Since less space is used in the buffers, compile time may increase. If V is specified on a 7600 control card, it will be ignored.

C COMPASS ASSEMBLY

The COMPASS assembler is used to assemble the code generated by FTN. If C is omitted, the FTN assembler is used; it is two to three times faster than the COMPASS assembler. When the C parameter is specified, FTNMAC is supplied as additional text for the COMPASS assembly. Therefore, if the C option is selected, the maximum number of system texts which can be specified with the GT and S parameters is six.

R SYMBOLIC REFERENCE MAP

(Default R = 1)

R = n Selects the kind of reference map required (section 14).
R = 0 No map
R = 1 Short map (symbols, addresses, properties)
R = 2 Long map (symbols, addresses, properties, references by line number and a DO-loop map)
R = 3 Long map with printout of common block members and equivalence groups

PL PRINT LIMIT

(Default n = 5000)

PL = n n is the maximum number of records produced by the user program at execution time which can be written on the OUTPUT file. n does not include the number of records in the source program listing, and compilation and execution time listings; n ≤ 999 999 999

PL = nB An octal number must be suffixed with a B; n ≤ 777 777 777B

Q PROGRAM VERIFICATION

Compiler performs full syntactic and semantic scan of the program and prints all diagnostics, but no object code is produced. A complete reference map is produced (with the exception of code addresses). This mode is substantially faster than a normal compilation; but it should not be selected if the program is to be executed. If Q is omitted, normal compilation takes place.
**Z  ZERO PARAMETER**

When Z is specified, all subroutine calls with no parameters are forced to pass a parameter list consisting of a zero word. This feature is useful only to COMPASS subroutines expecting a variable number of parameters (0 to 63). For example, CALL DUMP dumps storage on the OUTPUT file and terminates program execution. If no parameters are specified and Z is selected, a zero word parameter is passed. Z should not be specified unless necessary, as programs execute more efficiently if Z is omitted.

**LCM  LARGE CORE MEMORY ACCESS**

(Preferred LCM = D)

- **LCM = D**
  Selects 17-bit address mode for level 2 data. This method is the most efficient for generating code for data assigned to level 2. User LCM field length must not exceed 131,071 words.

- **LCM = I**
  Selects 21-bit address mode for level 2 data. This mode depends heavily upon indirect addressing. LCM = I must be specified if the user LCM field length exceeds 131,071 words.

In neither case can a single common block be greater than 131,071 decimal words.

**OPT  OPTIMIZATION PARAMETER**

**OPT = m**

- **m = 0**
  Fast compilation (automatically selects T option)

- **m = 1**
  Standard compilation and execution

- **m = 2**
  Fast execution

The level of optimization performed by the compiler is determined by the value of m.

- **OPT = 0**
  Compilation speed increases at expense of execution speed. (Selecting the D parameter automatically selects OPT = 0.)

- **OPT = 1**
  Normal compilation takes place.

- **OPT = 2**
  Execution speed increases for certain loops. Two types of optimization are performed:
    - Calculations which do not vary are removed from loops.
    - Variables and constants from the body of a loop are assigned to registers.
The degree of optimization of DO and IF loops varies according to the following constraints:

- It must be the innermost loop (contain no loops).
- It must contain no branching statements (GO TO, IF or RETURN) except a branch back to the start of the loop for IF loops.
- The loop does not contain BUFFER IN/BUFFER OUT or ENCODE/DECODE statements. If input/output or any external calls occur, only calculations which do not vary are removed.
- Control must flow to the statement following the end of the IF loop when it completes.
- Entry into the IF loop must be through the sequence of statements preceding the start of the loop.

**INVARIANT COMPUTATIONS**

In many instances, a programmer codes calculations which do not change on successive iterations within a loop. When these computations are moved outside the loop, the speed of the loop is improved without changing the results.

Example 1:

```plaintext
DO 100 I=1,2000
  100 A(I) = 3*I + J/K+5
```

A more efficient loop would be:

```plaintext
ITERM = J/K+5
DO 100 I = 1,2000
  100 A(I) = 3*I + ITERM
```

For clarity, the programmer may not wish to write the code in this form. However, if OPT=2 is specified the more efficient loop structure is produced by the compiler. A message is printed:

```
N WORDS OF IN Variant RLIST REMOVED FROM
THE LOOP STARTING AT LINE x
```

RLIST is the intermediate language of the compiler. The source language is translated first into RLIST, then into COMPASS. Optimization takes place during the RLIST phase, and it is at this point that invariant code is removed. The message notifies the programmer that his loop has been modified, and informs him of the magnitude of the change.
Example 2:

\[
I = 1 \\
200 \quad J = K+L+4 \\
A(I) = M+I \\
I = I+1 \\
IF(I.LE.100) G0 TO 200
\]

Use of OPT=2 produces code as if example 2 had been written as shown below:

\[
I=1 \\
J = K+L+4 \\
200 \quad A(I) = M+I \\
I = I+1 \\
IF(I.LE.100) G0 TO 200
\]

Example 3:

\[
DO 300 \quad I=1,2000 \\
A(I) = SQRT(FLOAT(I)) \\
A(I) = A(I) + 3.5*R \\
300 \quad CONTINUE
\]

The computation of 3.5*R is removed from the loop regardless of the external call. In general, this process will occur unless R is a parameter to the external routine, or R is in common. When a variable is a member of an equivalence group, its use is not recognized as invariant if another member of the group is referenced inside the loop by non-standard subscripts. For standard subscripts, optimization will occur, although the assumption is made that all subscripting is within the bounds of array specifications. A standard subscript is one of the following forms; c and k are integer constants and v is an integer variable.

\[
\begin{align*}
&c*v + k \\
&c*v - k \\
v + k
\end{align*}
\]

Subscript expressions which do not conform to the above are non-standard subscripts.

**REGISTER ASSIGNMENT**

For many loops, it is possible to keep commonly used variables and constants in the machine registers. Eliminating loads and stores from the body of the loop has two advantages:

- The reduced number of loads and stores increases execution speed.
- The loop is shortened and may fit in the instruction stack. A loop that fits in the instruction stack usually runs two to three times as fast as a comparable loop which does not fit in the stack.
Presently up to four X registers may be assigned over a loop. The number assigned depends on the number of candidates available for selection and the complexity of the operations performed within the loop. When registers are assigned, an informative message is printed:

\[ \text{n REGISTERS ASSIGNED OVER THE LOOP BEGINNING AT LINE x} \]

Register assignment will not be performed for loops containing external references.

Example:

<table>
<thead>
<tr>
<th>Loop</th>
<th>Without register assignment</th>
<th>With register assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO 100 I=1,2000</td>
<td>top of loop</td>
<td>top of loop</td>
</tr>
<tr>
<td>A(I) = 3.0</td>
<td>load 3.0</td>
<td>load 3.0</td>
</tr>
<tr>
<td>100 CONTINUE</td>
<td>store into A(I)</td>
<td>store into A(I)</td>
</tr>
<tr>
<td></td>
<td>end of loop test</td>
<td>end of loop test</td>
</tr>
</tbody>
</table>
Example:

<table>
<thead>
<tr>
<th>Loop</th>
<th>Without register assignment</th>
<th>With register assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>$X = 1.0$</td>
<td>$X = 1.0$</td>
<td>$X = 1.0$</td>
</tr>
<tr>
<td>DO 200 I=1,100</td>
<td>top of loop</td>
<td>load X</td>
</tr>
<tr>
<td>$X = X/.5+Y$</td>
<td>load X</td>
<td>load .5</td>
</tr>
<tr>
<td>$A(I) = X$</td>
<td>load .5</td>
<td>load Y</td>
</tr>
<tr>
<td>200 CONTINUE</td>
<td>$X/.5+Y$ result to register holding X</td>
<td>top of loop</td>
</tr>
<tr>
<td></td>
<td>store into X</td>
<td>store into A(I)</td>
</tr>
<tr>
<td></td>
<td>store into A(I)</td>
<td>end of loop test</td>
</tr>
<tr>
<td></td>
<td>end of loop test</td>
<td>store X</td>
</tr>
</tbody>
</table>
Example:

\[ \texttt{FTN (A, LRN, 0, S=0)} \]

Selects the following options:

- A: Branch to EXIT(S) card if compilation errors occur
- LRN: Source program, fatal diagnostics, and reference map are listed.
- G: Generated binary object file is executed at end of successful compilation.
- S = 0: When COMPASS is called to assemble an intermixed COMPASS subprogram, it will not read in a systems text file.

Example:

\[ \texttt{FTN(G, T)} \]

Source program on INPUT file, object code on LGO, normal listing on OUTPUT file, maximum error checking, no debug package, standard compile mode, and unrounded arithmetic. Program is executed if no fatal errors occur.

\texttt{FTN} is equivalent to \texttt{FTN(I=INPUT, L=OUTPUT, B=LGO, S=SYSTEAM, R=1, OPT=1)}
To reduce the amount of storage required, and to make more efficient use of his field length; a user can divide his program into overlays. Prior to execution, the sections of an overlay program are linked by the loader and placed on a mass storage device or tape file in their absolute form; no time is required for linking at execution time.

OVERLAYS

An overlay is a portion of a program written on a file in absolute form and loaded at execution time without relocation. As a result, the size of the resident loader for overlays can be reduced substantially. Overlays can be used when the organization of core can be defined prior to execution.

When each overlay is generated, the loading operation is completed by loading library and user subprograms and linking them together. The resultant overlay is in fixed format, in that internal references are fixed in their relationship to one another. The entire overlay has a fixed origin address within the field length and, therefore, is not relocatable. The overlay loader simply reads the required overlay from the overlay file and loads it starting at its pre-established origin in the user’s field length.

Overlays are loaded into memory at three levels: zero, primary, and secondary.

The zero or main overlay is loaded first and remains in core at all times. A primary overlay may be loaded immediately following the zero overlay, and a secondary overlay immediately following the primary overlay. Overlays may be replaced by other overlays. For example, if a different secondary overlay is required, the overlay loader simply reads it from the overlay file and places it in memory at the same starting address as the previously loaded overlay.
When a primary overlay is loaded, the previously loaded primary overlay and any of its associated secondary overlays are destroyed. Loading a secondary overlay destroys a previously loaded secondary overlay. Loading any primary overlay destroys any other primary overlay. For this reason, no primary overlay may load other primary overlays.

Overlays are identified by a pair of integers:

- zero or main overlay (0,0)
- primary overlay (n,0)
- secondary overlay (n,k)

n and k are positive integers in the range 0-77 octal. For any given program execution, all overlay identifiers must be unique.

For example, (1,0) (2,0) (3,0) (4,0) are primary overlays. (3,1) (3,2) (3,5) (3,7) are secondary overlays associated with primary overlay (3,0). Secondary overlays are denoted by the primary number and a non-zero secondary number. For example, (1,3) denotes that secondary overlay number 3 is related to primary overlay (1,0). (2,5) denotes secondary overlay 5 is related to primary overlay (2,0).

A secondary overlay can be called into core by its primary overlay or by the main overlay. Thus overlay (0,0) and overlay (1,0) may call (1,2); but overlay (2,0) may not call (1,2).

Overlay numbers (0,n) are not valid. For example, (0,3) is an illegal overlay number.

Execution is faster if the more commonly used subprograms are placed in the zero overlay, which remains in central memory/small core at all times, and the less commonly used subprograms are placed in primary and secondary overlays which are called into memory as required.
OVERLAY LINKAGES

The loader generates overlays and places them on a mass storage device or tape file in their absolute form. Linkage within an overlay is established during generation. The FORTRAN CALL statement (section 7) in a secondary overlay may call a subprogram within itself, or in its associated primary overlay, or in the zero overlay. Similarly, CALL statements in a primary overlay may call only subprograms within itself or in the zero overlay. Subprograms in the zero overlay may call only subprograms within the zero overlay. In order to call a primary or secondary overlay from a zero overlay, a CALL OVERLAY statement must be used.

An overlay may consist of one or more FORTRAN or COMPASS programs. The first program in the overlay must be a FORTRAN main program (not a subprogram). The program name becomes the primary entry point for the overlay when the overlay is called.

Data is passed between overlays through labeled or blank common. Any element of a labeled or blank common block in the main overlay (0,0) may be referenced by any higher level overlay. Any labeled or blank common declared in a primary overlay may be referenced only by the primary overlay and its associated secondary overlays—not by the zero overlay. If blank common is used for communicating between overlays, the user must ensure that sufficient field length is reserved to accommodate the largest loaded overlay in addition to blank common. Data stored in blank common must be used by each level of the overlay in exactly the same format, since no linkage is provided between the different levels of overlay and blank common at execution or load time.

Blank common is located at the top (highest address) of the first overlay in which blank common is declared. For example, if blank common is declared in the (0,0) overlay, it is located at the top of the (0,0) overlay and is accessible to all higher level overlays. If blank common is declared in the (1,0) overlay, it is allocated at the top of the (1,0) overlay and is accessible only to the associated (1,k) overlays. Labeled common blocks are generated in the overlay in which they are first encountered; data may only be preset in labeled common blocks in this overlay.

LCM common blocks must be defined and preset in the main (0,0) overlay. The entire overlay structure can reference an LCM common block.

CREATING AN OVERLAY

An overlay is established by an OVERLAY directive preceding the main program card for that overlay. An overlay consists of all programs appearing between its OVERLAY directive and the next OVERLAY directive or an end-of-file (6/7/8/9) card. The directive must be punched starting in column 7 or later and must be contained wholly on one card.
OVERLAY (fname,i,j,Cn)

file name

File name on which the generated overlay is to be written. All overlays need not reside on the same file.

i

Primary number, octal.

j

Secondary number, octal. (i and j must be 0,0 for the first overlay card.)

Cn

Optional parameter consisting of the letter C and a 6-digit octal number, which indicates the overlay is to be loaded n words from the start of blank common. Blank common is loaded after the zero overlay. With this method, the programmer can change the size of blank common at execution time. Cn cannot be included on the (0,0) overlay control card. If this parameter is omitted, the overlay is loaded in the normal way.

The first overlay directive must have a file name, subsequent directives may omit it, indicating that the overlays are related and are to be written on the same file.

Example:

```
OVERLAY(FNAME,0,0)
PROGRAM CAT(INPUT,OUTPUT,TAPE5=INPUT)
  .
  .
OVERLAY(1,0)
PROGRAM A
  .
  .
OVERLAY(1,1)
PROGRAM B
  .
  .
OVERLAY(1,2)
PROGRAM C
  .
  .
OVERLAY(1,3)
PROGRAM D
  .
  .
```

All the above overlays are written on the file FNAME.
Each OVERLAY directive must be followed by a PROGRAM statement. The PROGRAM statement for the zero or main overlay (0,0) must specify all file names such as INPUT, OUTPUT, TAPE1, etc., required for all overlay levels. File names should not appear in PROGRAM statements for other than the (0,0) OVERLAY.

Loading overlays from a file requires an end-around search of the file for the specified overlay; this can be time consuming in large files. When speed is essential, each overlay should be written on a separate file, or it should be called in the same order in which it was generated.

The group of relocatable decks processed by the loader must be presented to the loader in the following order. The main overlay must be loaded first. Any primary group followed by its associated secondary group can follow, then any other primary group followed by its associated secondary group, and so forth.

**CALLING AN OVERLAY**

A SCOPE control card causes the main (0,0) overlay to be loaded. Primary and secondary overlays are called by the following statement:

```
CALL OVERLAY (fname,i,j,recall,k)
```

- `fname` is the variable name of the location containing the name of the file. If format left justified display code; which includes the overlay if the k parameter is zero or is not specified. If a non-zero k parameter is specified, fname is the variable name of the location containing the overlay to be loaded.
- `i` Primary number of the overlay
- `j` Secondary number of the overlay
- `recall` Recall parameter. If 6HRECALL is specified, the overlay is not reloaded if it is already in memory. If the overlay is already in memory and the recall parameter is not used, the overlay is actually reloaded, thus changing the value of variables in the overlay.
- `k` can be either an I, format Hollerith constant of 7 characters, or any non-zero value. If k is a 7L... Hollerith constant, the overlay is loaded from the library named 7L... If k is any other non-zero value, the overlay is loaded from the global library set (refer to the SCOPE Reference Manual).

For example, the following statement causes a primary overlay to be loaded from the file named A:

```
CALL OVERLAY(1HA,1,0)
```
The following statement which specifies the \( k \) parameter as a non-zero value causes a main overlay, with the name BJR, to be loaded from the global library set.

\[
\text{CALL OVERLAY}(3\text{HBJR},0,0,0,1)
\]

Numbers in the OVERLAY card are octal, thus to call OVERLAY (SAM,1,11) the statement CALL OVERLAY (3HSAM,1,9,0) or CALL OVERLAY (3HSAM,1,11B,0) must be used.

The three parameters, \( f \)name, \( i \), and \( j \) must be specified; if any is omitted, a MODE error could result at execution time.

When an END statement is encountered in the main program of an overlay, control returns to the statement following the CALL OVERLAY statement.

Example:

\[
\begin{align*}
\text{OVERLAY(XFILE,0,0)} \\
\text{PROGRAM ONE(INPUT,OUTPUT,PUNCH)} \\
. \\
. \\
. \\
\text{CALL OVERLAY(5HFILE,1,0,0)} \\
. \\
. \\
\text{STOP} \\
\text{END} \\
\text{OVERLAY(XFILE,1,0)} \\
\text{PROGRAM ONE ZERO} \\
\text{CALL OVERLAY(5HFILE,1,1,0)} \\
. \\
. \\
\text{RETURN} \\
\text{END} \\
\text{OVERLAY(XFILE,1,1)} \\
\text{PROGRAM ONE ONE} \\
. \\
. \\
\text{RETURN} \\
\text{END}
\end{align*}
\]
Example:

Preparation of Overlay 0,0; 1,0; and 1,1
The above example illustrates the preparation of zero primary and secondary overlays. The zero overlay, FRANK.0.0, consists of a main program LEO and a subroutine GROUCH. The primary overlay FRANK.1.0 consists of a main program MLT and a data deck. All three overlays reside on the file FRANK.

The SCOPE control card LOAD(LGO) requests the loader to load the program from the file LGO. As the loader reads file LGO, it encounters the overlay directive OVERLAY (FRANK,0.0) which instructs it to create a main overlay from the program and write it on file FRANK. When the absolute form of all the overlays has been generated, execution begins when the SCOPE control card FRANK is encountered. FRANK causes the main overlay to be loaded from file FRANK and executed.

During execution of the main overlay, the CALL OVERLAY (5HFRANK,1.0,0) statement is encountered and the primary overlay 1.0 is loaded into central memory. The CALL OVERLAY (5HFRANK,1.1) statement in the primary overlay causes the secondary overlay to be loaded into memory.

The primary and secondary overlays can reside on files other than FRANK. For example, the primary overlay could be on file JIM and the secondary overlay on file JOHN.

```
FIN.
LGO.
FRANK.
789
OVERLAY (FRANK,0,0)
PROGRAM LEO (INPUT,OUTPUT,TAPE1)
.
.
.
CALL OVERLAY (3HJIM,1,0,0)
.
.
.
OVERLAY (JIM,1,0)
PROGRAM RDY
.
.
.
CALL OVERLAY (4HJOHN,1,1,0)
END
OVERLAY (JOHN,1,1)
PROGRAM MLT
.
.
.
END
```

Example:

The following program, which contains several subroutines and functions, is to be used repeatedly. The entire program can be generated, therefore, as a main overlay and placed on the file in its absolute form. The SCOPE control card CATALOG creates a permanent file OVRLY where the
absolute form of the program will be kept. When the program is required again the SCOPE permanent file OVRLY is called by an ATTACH control card.

The first program must be a main program; in this case program A.

```
FTN.
LOAD(LGO)
CATALOG (OVRLY,REPEAT,ID=IBB)
NAGO.
7/8/9
OVERLAY (REPEAT,0,0)
PROGRAM A (INPUT,OUTPUT,TAPE1)
.
.
END
SUBROUTINE B
.
.
.
END
FUNCTION C
.
.
.
.
.
.
END
SUBROUTINE D
.
.
.
.
.
.
.
.
.
END
REAL FUNCTION E

.
The debugging facility allows the programmer to debug programs within the context of the FORTRAN language. Using the statements described in this section, the programmer can check the following:

Array bounds
Assigned GO TO
Subroutine calls and returns
Function references and the values returned
Values stored into variables and arrays
Program flow

The debugging facility, together with the source cross reference map, is provided specifically to assist the programmer develop or convert programs.

The debugging mode is selected by specifying D or D=Iftn on the FTN control card (section 11). This control card parameter automatically selects fast compilation (OPT=0) and full error traceback (T option). If any other optimization level is specified, it will be ignored. The following examples are equivalent:

\[
\begin{align*}
\text{FTN} \ (D) \\
\text{FTN} \ (D=\text{INPUT}, \text{OPT}=0, T) \\
\text{FTN} \ (D, \text{OPT}=2) & \text{ OPT}=2 \text{ is ignored, OPT}=0 \text{ and T are automatically selected.}
\end{align*}
\]

Debug output is written on the file DEBUG. When the job terminates, SCOPE gives the DEBUG file a print disposition and it is printed separately from the output file. To obtain debugging information on the same file as the source program, or any other file, DEBUG must be equivalenced to that file in the PROGRAM statement.

Examples:

\[
\begin{align*}
\text{PROGRAM EX (INPUT, OUTPUT, DEBUG=OUTPUT)}
\end{align*}
\]

Debug output is interspersed with program output on the file OUTPUT.

\[
\begin{align*}
\text{PROGRAM EX (INPUT, OUTPUT, TAPEX, DEBUG=TAPEX)}
\end{align*}
\]

Debug output is written on the file TAPEX.
The following control card sequence causes the debug output to be printed on the output file at termination of the job. It will not be interspersed with program output.

```
FTN(D)
LGO.
REWIN(DEBUG)
COPYCF(DEBUG,OUTPUT)
EXIT(S)     Abnormal termination
REWIN(DEBUG)
COPYCF(DEBUG,OUTPUT)
```

When the debug mode is selected, programs execute regardless of compilation errors. Execution will, however, terminate at that point in the program where a fatal error is detected, and the following message will be printed:

```
FATAL ERROR ENCOUNTERED DURING PROGRAM EXECUTION
DUE TO COMPILATION ERROR
```

Partial execution is prohibited for only three classes of errors.

- Errors in specification statements
- Missing DO loop terminators
- Missing FORMAT statement numbers

Partial execution of programs containing fatal errors allows the programmer to insert debugging statements in his program to assist him in locating fatal and non-fatal errors.

When a program is compiled in debug mode, at least 12000 (octal) words will be required beyond the minimum field length for normal compilation. To execute, at least 2500 (octal) words beyond the minimum would be required. The CPU time required for compilation will also be greater than for normal OPT=0 compilation.

If the D option is not specified on the FTN control card, all debugging statements are treated as comments. Therefore, it is not necessary to remove the debugging statements after the program is sufficiently debugged.
All debugging options are activated and deactivated at compile time only. This compile time processing is not to be confused with program flow at execution time.

```
PROGRAM TEST (OUTPUT,DEBUG-OUTPUT)
  .
  .
  .
  GO TO 4
  .
  .
  .
  CS (DEBUGGING OPTION)
  CS (DEBUGGING OPTION)
  .
  .
  .
  4 CONTINUE
  .
  .
  .
  END
```

Even though a section of code may never be executed, the debugging options are processed at compile time and are effective for the remainder of the program. In the above example, the code between the GO TO statement and the CONTINUE statement may never be executed. However, debugging statements between these statements are processed at compile time and are effective for the remainder of the program, or until deactivated by a CS OFF statement.

**DEBUGGING STATEMENTS**

```
1    7
CS   ds(p_1, . . . , p_n)
```

- **ds**: Type of option, beginning after column 6: DEBUG, AREA, ARRAYS, CALLS, FUNCS, GOTOS, NOGO, OFF, STORES, TRACE
- **p_i**: Argument list; details extent of the option, ds (not used with NOGO, GOTOS; required for AREA, STORES; optional for other options)
CONTINUATION CARD

Debugging statements are written in columns 7-72, as in a normal FORTRAN statement, but columns 1 and 2 of each statement must contain the characters CS. Any character, other than a blank or zero, in column 6 denotes a continuation line. Columns 3, 4, and 5 of any debugging statement must be blank. The restriction on the number of continuation lines is the same as for FORTRAN continuation lines.

Comment cards may be interspersed with debugging statements. The statement separator ($) cannot be used with debugging statements. When the debug mode is not selected, all debugging statements are treated as comments.

Example:

C$  ARRAYS (A, BNUMB,Z10, C, DLIST, MATRIX,  
C$  *NSUM, GTEXT,  
C$  *TOTAL)

ARRAYS STATEMENT

The ARRAYS statement initiates subscript checking on specified arrays. If no argument list specified, all arrays in the program unit are checked. Each time a specified or implied element of an array is referenced, the calculated subscript is checked against the dimensioned bounds. The address is calculated according to the method described in figure 2-1, section 2. Subscripts are not checked individually. If the address is found to be greater than the storage allocated for the array or less than one, a diagnostic is issued. The reference is then allowed to continue. Bounds checking is not performed for array references in input/output statements, or in ENCODE/DECODE statements.
PROGRAM ARRAYS (OUTPUT, DEBUG=OUTPUT)
INTEGER A(2), B(4), C(6), D(2,3,4)
PRINT 1
1 FORMAT(*0, ARRAYS EXAMPLE*/*/)

TURN ON ARRAYS FOR ARRAYS A AND D

C$
ARAYS (A, D)

A(3) IS OUT OF BOUNDS AND ARRAYS IS ON FOR A, SO A DIAGNOSTIC
IS PRINTED.
A(3) = 1

B(5) IS OUT OF BOUNDS BUT ARRAYS IS NOT ON FOR B, SO NO
DIAGNOSTIC IS PRINTED.
B(5) = 1
C(2) = A(A(3))

EVEN THOUGH A(3) WAS OUT OF BOUNDS, THE ASSIGNMENT TOOK PLACE.
A(A(3)) IS EQUIVALENT TO A(1), THIS SUBSCRIPT IS IN BOUNDS,
HOWEVER THE REFERENCE TO A(3) WILL CAUSE A DIAGNOSTIC.

D(-5,0,6) = 99

FOR THE ARRAY D(L,M,N) THE STORAGE ALLOCATED IS L * M * N.
THE ADDRESS OF THE ELEMENT D(I,J,K) IS COMPUTED AS FOLLOWS
(I + L + (J - 1 + M + (K - 1)))
FOR THE ELEMENT D(-5,0,6) THE SUBSCRIPT APPARELS TO
BE OUT OF BOUNDS BECAUSE THE INDIVIDUAL SUBSCRIPTS ARE OUT
OF BOUNDS. HOWEVER, 23, THE COMPUTED ADDRESS, IS LESS THAN
24, THE STORAGE ALLOCATED, AND NO DIAGNOSED IS ISSUED.

TURN ON ARRAYS FOR ALL ARRAYS

C$
ARAYS

WITH THIS FORM ALL ARRAY REFERENCES WILL BE CHECKED. THERE WILL
BE DIAGNOSTICS FOR B(5), C(-1), AND D(0,0,0). BECAUSE A(2)
IS IN BOUNDS AND A(4) IS IN AN I/O STATEMENT, THERE WILL BE
NO DIAGNOSTICS FOR EITHER OF THESE REFERENCES.

A(2) = 1
B(5) = 2 + C(-1)
D(0,0,0) = 1
PRINT 2, A(4)
2 FORMAT(1X, A10)
END
CALLS STATEMENT

\( \text{CALLS} \left( a_1, \ldots, a_n \right) \)

\( a_1, \ldots, a_n \) subroutine names

The CALLS statement initiates tracing of calls to and returns from specified subroutines. If there is no argument list all subroutines will be traced. Non-standard returns, specified in a RETURNS list, are included. To trace alternate entry points to a subroutine, either the entry points must be explicitly named in the argument list, or the form with no argument list must be used (all external calls traced). The message printed contains the names of the calling and called routines, as well as the line and level number of the call and return.

A main program is at level zero; a subroutine or a function called by the main program is at level 1. another subprogram called by the subprogram at level 1, is at level 2, and so forth. Calls are shown in order of ascending level number, returns in order of descending level number.

For example, subroutine SUB A is called at level 1 and a return is made to level 0. SUB B is called at level 2 and a return is made to level 1.
Example:

```plaintext
PROGRAM CALLS (OUTPUT, DEBUG=OUTPUT)
  PRINT 1
    1 FORMAT (*0      CALLS TRACING*)
  *
  **
  ** TURN ON CALLS FOR SUBROUTINES CALLS1 AND CALLS2
  **
  ** CALLS(CALLS1, CALLS2)
  **
    X = 1
    CALL CALLS1 (X,Y), RETURNS (10)
  10 IF (X .EQ. 1.) CALL CALLS2
    CALL SUBNOT
    CALL CALLS1E (X,Y)
    *
    *
    * DEBUG MESSAGES WILL BE PRINTED FOR CALLS TO AND RETURNS FROM
    * CALLS1 AND CALLS2. SINCE THE CALLS ARE FROM THE MAIN PROGRAM,
    * THEY ARE AT LEVEL 0. THE CALLS TO SUBNOT AND THE ALTERNATE
    * ENTRY POINT CALLS1E ARE NOT TRACED BECAUSE THEY DO NOT APPEAR
    * IN THE ARGUMENT LIST OF THE CALLS STATEMENT.
    *
    *
  **
  ** TURN ON CALLS FOR ALL SUBROUTINES
  **
  ** CALLS
  25 CALL SUBNOT
  25 CALL CALLS2
    CALL CALLS1E (X,Y)
    *
    *
    * DEBUG MESSAGES WILL BE PRINTED FOR CALLS TO AND RETURNS FROM
    * SUBNOT, CALLS2, AND CALLS1E, SINCE ALL CALLS ARE TO BE
    * TRACED.
  30 END

SUBROUTINE CALLS1 (X,Y), RETURNS(A)
  Y = -X
  IF (Y .NE. X) RETURN A
  RETURN
  ENTRY CALLS1E
  RETURN
END

SUBROUTINE CALLS2
  CALL CALLS1 (X,Y), RETURNS(S)
  RETURN
END

SUBROUTINE SUBNOT
  X = -1.
  CALL CALLS1 (X,Y), RETURNS(S)
  RETURN
END
```

60305600 A

I-13-7
CALLS TRACING

/DEBUG/ CALLS AT LINE 9- ROUTINE CALLS1 CALLED AT LEVEL 0
/DEBUG/ AT LINE 10- ROUTINE CALLS1 RETURNS TO LEVEL 0 AT STATEMENT 10
/DEBUG/ AT LINE 11- ROUTINE CALLS2 CALLED AT LEVEL 0
/DEBUG/ AT LINE 24- ROUTINE SUBNOT CALLED AT LEVEL 0
/DEBUG/ AT LINE 25- ROUTINE SUBNOT RETURNS TO LEVEL 0
/DEBUG/ AT LINE 26- ROUTINE CALLS2 CALLED AT LEVEL 0
/DEBUG/ AT LINE 27- ROUTINE CALLS1E CALLED AT LEVEL 0
/DEBUG/ AT LINE 27- ROUTINE CALLS1E RETURNS TO LEVEL 0

In this example, only calls from the main program are traced. To trace calls from subprograms, a CS CALLS statement must appear in the subprograms.

FUNCS STATEMENT

If no function names \((a_1, \ldots, a_n)\) are listed, all external functions referenced in the program unit are traced. Alternate entry points must be named explicitly in the argument list, or implicitly in the CS FUNCS statement with no parameterers.

Function tracing is similar to call tracing, but the value returned by the function is included in the debug message. Each time a specified external function is referenced, a message is printed which contains the routine name and line number containing the reference, function name and type, value returned and level number. The level concept is the same as for the CALLS statement.

Statement function references are not traced nor are function references in input/output statements.
Example:

The following program, VARDIM2, illustrates both the CS FUNCS and CS CALLS statements. All function references in the main program are traced because CS FUNCS appears without an argument list; references to functions PVAL, AVG and MULT and the values returned to the main program (level 0) are traced. All subroutines in the main program are traced also because a CS CALLS statement without an argument list appears.

Function references within the FUNCTION subprograms PVAL, AVG and MULT are traced since CS FUNCS statements appear within these subprograms. If no CS FUNCS statements appear in the subprograms, only main program function references will be traced.

```fortran
PROGRAM VARDIM2 (OUTPUT, TAPE6=OUTPUT, DEBUG=OUTPUT)
  ** THIS PROGRAM USES VARIABLE DIMENSIONS AND MANY SUBPROGRAM CONCEPTS **
  COMMON X(4,3)
  REAL Y(6)
  EXTERNAL MULT, AVG
  PVALSF(X,Y) = PVAL(X,Y)
  CALLS
  CALL SET(Y,6,0.)
  CALL IOTA(X,1?)
  CALL INC(X,12,-5.)
  CALLS
  ALL EXTERNAL CALLS ARE DIAGNOSED.
  CALLS
  FUNCS
  A = PVALSF(12,AVG)
  AM = PVALSF(12,MULT)
  PVALSF IS A STATEMENT FUNCTION, SO THE FUNCS STATEMENT DOES NOT APPLY TO IT AND NO MESSAGE IS PRINTED. HOWEVER, THE EXTERNAL FUNCTION PVAL IS REFERENCED WITHIN THE CODE FOR PVALSF, AND THOSE REFERENCES ARE DIAGNOSED.
  MULT AND AVG ARE NAMES AS ARGUMENTS TO PVALSF, HOWEVER, THE FUNCTIONS ARE NOT ACTUALLY REFERENCED AND MESSAGES ARE NOT PRINTED.
  STOP
END
```

SUBROUTINE SET (A, M, V)
  SET PUTS THE VALUE V INTO EVERY ELEMENT OF THE ARRAY A
  DIMENSION A(M)
  DO I = 1, M
  A(I) = V
END

ENTRY INC
  INC ADDS THE VALUE V TO EVERY ELEMENT IN THE ARRAY A
  DO II = 1, M
  A(I) = A(I) + V
RETURN
END
SUBROUTINE IOTA (A, M)
C IOTA PUTS CONSECUTIVE INTEGERS STARTING AT 1 IN EVERY ELEMENT OF
C THE ARRAY A
      DIMENSION A(M)
      DO11=1,M
      A(I)=I
      END

FUNCTION PVAL(SIZE,WAY)
C PVAL COMPUTES THE POSITIVE VALUE OF WHATEVER REAL VALUE IS RETURNED
C BY A FUNCTION SPECIFIED WHEN PVAL WAS CALLED. SIZE IS AN INTEGER
C VALUE PASSED ON TO THE FUNCTION.
      INTEGER SIZE
      C$ FUNC(SABS)
      PVAL=ABS(WAY(SIZE))
      C WAY DOES NOT APPEAR IN THE ARGUMENT LIST FOR THE FUNC(S) STATEMENT,
      C SO ONLY THE REFERENCE TO ABS IS DIAGNOSED.
      RETURN
      END

FUNCTION AVG(J)
C AVG COMPUTES THE AVERAGE OF THE FIRST J ELEMENTS OF COMMON.
      COMMON A(100)
      AVG=0.
      DO11=1,J
      AVG=AVG+A(I)
      C$ FUNC
      C ALL EXTERNAL FUNCTION REFERENCES WILL BE DIAGNOSED.
      AVG=AVG/FLOAT(J)
      RETURN
      END

REAL FUNCTION MULT(J)
C MULT COMPUTES A STRANGE AVERAGE. IT MULTIPLIES THE FIRST AND 12TH
C ELEMENTS OF COMMON AND SUBTRACTS FROM THIS THE AVERAGE (COMPUTED
C BY THE FUNCTION AVG) OF THE FIRST J/2 WORDS IN COMMON.
      COMMON ARRAY(12)
      C$ FUNC
      C ALL EXTERNAL FUNCTION REFERENCES WILL BE DIAGNOSED.
      MULT=ARRAY(12)*ARRAY(1)-AVG(J/2)
      RETURN
      END
/DEBUG/ VARDIM2 AT LINE  8- ROUTINE SET CALLED AT LEVEL 0

STORES STATEMENT

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>7</td>
</tr>
<tr>
<td>C$</td>
<td>STORES (c_1, c_2, ..., c_n)</td>
</tr>
</tbody>
</table>

An argument list must be specified for the STORES statement. 

(c_1, ..., c_n) are variable names or expressions in the forms:

- variable name
- variable name .relational operator. constant
- variable name .relational operator. variable name
- variable name .checking operator

Relational operators are .EQ., .NE., .GT., .GE., .LT., .LE.

Checking operators are .RANGE., .INDEF., .VALID.

Example:

C$ STORES(SUM, DGAMP, AX, NET.LT.4, ROWSUM>RANGE.)

C$ STORES(A1, AGAIN, I, A2.EQ.5, IAGAIN.LE.IVAR)

C$ STORES(G.EQ.(-1,1),L VALID, D.NE.10.004)

C$ STORES(G.RANGE, TR.EQ..FALSE.)

60305600 A I-13-11
The STORES statement is used to record changes in value of specified variables or arrays. The STORES statement applies only to assignment statements. Values changed as a result of input/output, or use in DATA, ASSIGN, COMMON, or argument lists to subroutines and functions are not detected. The STORES statement does not apply to the index variable in a DO loop.

If the value of a variable in an EQUIVAENCE group is changed, the STORES statement will not detect changes to the value of other variables in the group.

VARIABLE NAMES

In the first form of the STORES statement, a message is printed each time the value of a variable or an array element changes. The variable and name of the array must appear as arguments in the CS STORES statement.

Example:

```
PROGRAM STORES (INPUT,OUTPUT,DEBUG = OUTPUT)
LOGICAL L1,L2
CS$ STORES (NSUM,DGAMP,AX)
NSUM = 20
DGAMP = .5
AX = 7.2 + DGAMP
L1 = .TRUE.
L2 = .FALSE.
PLANT = 2.5
A = 7.5
PRINT 3
3 FORMAT (1H0)
STOP
END
```

Each time the value of the variables NSUM, DGAMP and AX changes, a message is printed. The values of PLANT, A, L1 and L2 are not printed, since they do not appear in the argument list.
Array element names should not be specified in the parameter list of a STORES statement; the array name must be used. If an array element name appears, an informative diagnostic is printed.

Example:

```
PROGRAM STORAR (INPUT,OUTPUT,DEBUG=OUTPUT)
REAL A(10), B(4,2)
CS
STORES (A,B)
B(1,2) = 5.5
B(4,2) = 0.
DO 4 N = 1,3
  4 A(N) = N+1
PRINT 5
STOP
END
```

```
/DEBUG/  STORAR AT LINE   4- THE NEW VALUE OF THE VARIABLE B IS 5.500000000
/DEBUG/  AT LINE   5- THE NEW VALUE OF THE VARIABLE B IS 0.
/DEBUG/  AT LINE   7- THE NEW VALUE OF THE VARIABLE A IS 3.000000000
/DEBUG/  AT LINE   7- THE NEW VALUE OF THE VARIABLE A IS 4.000000000
```

The values stored into array elements B(1,2) and B(4,2) appear in the debug output under the array name B in both cases, and array elements A(1), A(2), and A(3) appear under the array name A.

**RELATIONAL OPERATORS**

In the second form of the CS STORES statement, a message is printed only when the stored value satisfies the relation specified in the argument list.

```
PROGRAM ST3 (INPUT,OUTPUT,DEBUG=OUTPUT)
5 FORMAT (1H0)
PRINT 5
M = 5
CS
STORES (I.EQ.3,N.LE.M*ANT)
I = 3
I = 4
N = 4
N = 6
J = 10
ANT = 77.0
END
```

```
/DEBUG/  ST3 AT LINE   6- THE NEW VALUE OF THE VARIABLE I IS 3
/DEBUG/  AT LINE   8- THE NEW VALUE OF THE VARIABLE N IS 4
/DEBUG/  AT LINE 11- THE NEW VALUE OF THE VARIABLE ANT IS 77.00000000
```

60305600 A
I appears in the debug output when it is equal to 3; N appears when it is less than or equal to M. Since no relational operator is specified with ANT, it is printed whenever the value changes.

CHECKING OPERATORS

In the third form of the STORES statement, a message is issued only when the stored value is out of range, indefinite, or invalid as specified by the checking operator.

- **RANGE** Out of range
- **INDEF** Indefinite
- **VALID** Out of range or indefinite

For example:

```
C$ STORES (ROWSUM .RANGE., COLSUM .VALID.)
```

Whenever the value to be stored into ROWSUM is out of range, a message is printed. Whenever the value to be stored into COLSUM is out of range or indefinite, a message is printed.

HOLLERITH DATA

Hollerith data stored in a variable of type integer is interpreted by the STORES statement as an integer number. Hollerith data stored in a variable of type real or double precision is interpreted as a real or double precision number.

In the following example, the three integer variables IHOLL, IRIGHT and ILEFT contain the characters PA in display code (20 and 01).

- **IHOLL** 20015555555555555555
  - PA blank fill
- **IRIGHT** 00000000000000000002001
  - zero fill PA
- **ILEFT** 2001000000000000000000
  - PA zero fill

The Hollerith characters PA are interpreted as integer numbers. Since the values stored in IHOLL and ILEFT are greater than 2**48-1, an X is printed (section 9.1w Output). The variable IRIGHT contains the value 2001 (octal) which is printed out by the STORES option in decimal as 1025.

The variable IHOLL is interpreted as a floating point number and its decimal value is printed.
Example:

```plaintext
PROGRAM DEHOL (INPUT, OUTPUT, DEBUG=OUTPUT)
C$ DEBUG
C$ STORES(IHOL, IRIGHT, ILEFT, HOLL)
5  IHOL=2HPA
   IRIGHT=2PPA
   ILEFT=2LPA
   HOLL=2HPA
10  PRINT 1
    1 FORMAT (I40)
    STOP
    END
```

```plaintext
/DEBUG/ DEHOL AT LINE 6- THE NEW VALUE OF THE VARIABLE IHOL IS X
/DEBUG/ DEHOL AT LINE 7- THE NEW VALUE OF THE VARIABLE IRIGHT IS 1025
/DEBUG/ DEHOL AT LINE 8- THE NEW VALUE OF THE VARIABLE ILEFT IS X
/DEBUG/ DEHOL AT LINE 9- THE NEW VALUE OF THE VARIABLE HOLL IS 4.021071096E+15
```

**GOTOS STATEMENT**

```
1  7
```

No argument list must be specified with the CS GOTOS statement. The GOTOS statement initiates checking of all assigned GO TO statements to ensure that the statement label assigned to the integer variable is in the GO TO statement list. If no match is found, a message is printed and transfer of control continues.

```
PROGRAM GOTOS (OUTPUT, DEBUG=OUTPUT)
INTEGER A
C$ GOTOS
5  * (GOTOS NEVER USES AN ARGUMENT LIST)
   ASSIGN 1 TO A
   GO TO 4 (1, 2, 3)
   * IN THIS CASE NO MESSAGE IS PRINTED SINCE THE LABEL ASSIGNED TO A IS IN THE GOTO LIST.
10  *
   4 PRINT 10
   10 FORMAT (* --CONTROL TRANSFERED TO STATEMENT LABEL 4--)
   STOP
15  1 ASSIGN 4 TO A
   GO TO 4 (1, 2, 3)
   * IN THIS CASE A MESSAGE IS PRINTED SINCE THE LABEL 4 IS NOT IN
   * THE GOTO LIST. CONTROL THEN TRANSFERS TO LABEL 4.
20  *
    2 CONTINUE
    3 CONTINUE
    END
```

```plaintext
/DEBUG/ GOTOS AT LINE 16- ASSIGNED GOTO INDEX CONTAINS THE ADDRESS 882451. NO MATCH FOUND IN STATEMENT LABEL ADDRESS LIST
   --CONTROL TRANSFERED TO STATEMENT LABEL 4--
```

60305600 A
TRACE STATEMENT

lv is a level number 0-49. If lv = 0, tracing occurs only outside DO loops. If lv = n, tracing occurs up to and including level n in a DO nest. If no level is specified, tracing occurs only outside DO loops.

The CS TRACE statement traces the following transfers of control within a program unit:

    GO TO
    Computed GO TO
    Assigned GO TO
    Arithmetic IF
    True side of logical IF

Transfers resulting from a return specified in a RETURNS list are not traced. (These can be checked by the CS CALLS statement.)

If an out-of-bound computed GO TO is executed, the value of the incorrect index is printed before the job is terminated.

Messages are printed each time control transfers during execution. The message contains the routine name, the line where the transfer took place, and the number of the line to which the transfer was made, as well as the statement number of this line, if present.

A message is printed each time control transfers at a level less than or equal to the one specified by lv. For example, if a statement CS TRACE(2) appears before a sequence of DO loops nested four deep, tracing takes place in the two outermost loops only.

TRACE messages are produced at execution time, but TRACE levels are assigned at compile time; therefore, the compile time environment determines the tracing status of any given statement. For example, a DO loop TRACE statement applies only to control transfers occurring between the DO statement and its terminal statement at compile time (physically between the two in the source listing).
Example:

```
PROGRAM P(OUTPUT,DEBUG=OUTPUT)
DATA J/0/

    TRA((1)
      IF (J.EQ. 0) GO TO 11
    11  DO 11 I1 = 1, 3
      IF ( (J+1).EQ. I1 ) GO TO 12
      J = 1
      DO 2 I2 = 1, 5
      J = J + I2
      GO TO 2
    10  CONTINUE

    CS  TRA((3)
      DO 20 I2 = 1, 3
      J = I2
      IF ( (J).GT. 13 ) GO TO 31
      GO TO 4
    20  CONTINUE

    30  CONTINUE
    31  CONTINUE
    25  CONTINUE
    END
```

In the first level 2 loop no debug messages are printed since the TRACE(1) statement is in effect. However, when the TRACE(3) statement becomes effective, flow is traced up to and including level 3. There are no messages for transfers within the level 4 loop. To trace only inner loops, for example levels 3 and 4 in the above example, a CS TRACE(4) statement is placed immediately before the DO statement for the level 3 loop (line 16). A CS OFF (TRACE) statement is placed after the terminal line for the level 3 loop, so that subsequent program flow in levels 0, 1, and 2 is not traced.
The level number applies to the entire program unit; it is not relative to the position of the CS TRACE statement in the program. For example, to trace the level 4 DO loop in Program P

```
CS TRACE(4)
```

must be specified. Positioning the statement CS TRACE(1) before statement 31 would not achieve the same result.

Care must be taken with the use of debugging statements within DO loops. Since nested loops are executed more frequently, the quantity of debug output may quickly multiply.

The CS TRACE (IV) statement traces transfers of control within DO loops. However, transfers between the terminal statement and the DO statement are not traced.

Example:

```
DO 100 I = 1,10
  .
  .
  .
100 CONTINUE
```

Transfers from statement 100 to the DO statement are not traced.

**NOGO STATEMENT**

![NOGO Diagram]

No argument list must be specified with this statement. The NOGO statement suppresses partial execution of a program containing compilation errors.

When the debug mode is specified and the NOGO statement is not present, programs execute regardless of compilation errors until a fatal error is encountered.

If a NOGO statement is present anywhere in the program, it applies to the entire program. It is therefore not affected by an OFF statement or by bounds in an AREA statement.
DEBUG DECK STRUCTURE

Debugging statements may be interspersed with FORTRAN statements in the source deck of a program unit (main program, subroutine, function). The debugging statements apply to the program unit in which they appear. Interspersed debugging statements (figure 13-1) change the FORTRAN generated line numbers for a program.

Debugging statements also may be grouped to form a debugging deck in one of the following ways:

As a deck placed immediately after the PROGRAM, SUBROUTINE or FUNCTION statement heading the routine to which the deck applies (internal debugging deck, figure 13-3). Any names specified in the DEBUG statement, other than the name of the enclosing routine, are ignored.

As a deck immediately preceding the first source deck in the job INPUT file (external debugging deck, figure 13-2).

As one or more decks on the file specified by the D parameter on the FTN control card (external debugging deck, figure 13-4). When no name is specified by the D parameter, the INPUT file is assumed.

All debugging decks must be headed by a CS DEBUG card. In an internal debugging deck, the CS DEBUG card is used without an argument list, since the deck can only apply to the routine in which it is inserted. In an external debugging deck, a CS DEBUG may be used with or without an argument list. The statements in the external debugging deck apply to all program units in the compilation.
Debugging cards are interspersed; they are inserted at the point in the program where they will be activated.

Figure 13-1. Example of Interspersed Debugging Statements
The external debugging deck is placed immediately in front of the first source line. All program units (here, Program A and Subroutine B) will be debugged (unless limiting bounds are specified in the deck). This positioning is particularly useful when a program is to be run for the first time, since it ensures that all program units will be debugged.

Figure 13-2. External Debugging Deck
When the debugging deck is placed immediately after the program name card and before any specification statements, all statements in the program unit will be debugged (unless limiting bounds are specified in the deck); no statements in other program units will be debugged. This positioning is best when the job is composed of several program units known to be free of bugs and one unit that is new or known to have bugs.

Figure 13-3. Internal Debugging Deck
The debugging deck is placed on a separate file (external debugging deck) named by the D parameter on the FTN control card and called in during compilation. All program units will be debugged (unless the program units to be debugged are specified in the deck). This positioning is useful when several jobs can be processed using the same debugging deck.

Figure 13-4. External Deck on Separate File
DEBUG STATEMENT

name₁,...,nameₙ routines to which the debugging deck applies

Internal and external debugging decks start with a DEBUG statement and end with the first card other than a debugging statement or comment. Interspersed debugging statements do not require a DEBUG statement.

In an internal debugging deck, the first form CS DEBUG statement without an argument list is generally used, since the deck can apply only to the program unit in which it appears. If a name is specified it must be the name of the routine containing the debugging deck; if any other name is specified, an informative diagnostic is printed.

In an external debugging deck, if no names are specified, the deck applies to all routines compiled. Otherwise, it will apply to only those program units specified by name₁,...,nameₙ; if any other name is specified, an informative diagnostic is printed.

Example:

In the following program, a DEBUG statement is not required since the debugging statement, CS STORES (A,B), is interspersed.

```
PROGRAM STORAR (INPUT,OUTPUT,DEBUG=OUTPUT)
REAL A(10), B(4,2)
CS
STORES (A,B)
B(1,2) = 5.5
B(4,2) = 0.
DO 4 N = 1,3
  A(N) = N+1
  PRINT 5
  FORMAT (1H0)
4      END
```

Example:

In the following program, a DEBUG statement is not required since the debugging statement, CS STORES (A,B), is interspersed.
However, if the CS STORES statement follows the PROGRAM statement, this is an internal debugging deck, and a CS DEBUG statement must appear.

```
PROGRAM DEHOL (INPUT,OUTPUT,DEBUG=OUTPUT)

C$ DEBUG
C$ STORES(IHOL,IRIGHT,ILEFT,HOLL)

IHOL=2HPA
IRIGHT=2RPA
ILEFT=2LPA
HOLL=2HPA

PRINT 1
1 FORMAT (1H0)
STOP
END
```

There can be several DEBUG statements in an external deck, and a routine can be mentioned more than once.

```
C$ DEBUG
C$ STORES(I,J)
C$ DEBUG(MAIN,EXTRA,NAMES)
C$ ARRAYS(VECTAB,MLTAB)
C$ DEBUG(MAIN)
C$ TRACE
C$ CALLS(EXTRA,NAMES)
```
AREA STATEMENT

CS AREA(bounds₁,...,boundsₙ) is used in internal debugging decks only.

name₁,name₂,...,nameₙ are the names of routines to which the following bounds apply.

bounds are line positions defining the area to be debugged.

bounds can be written in one of the following forms:

(n₁,n₂)  n₁ Initial line position
         n₂ Terminal line position

(n₃)     n₃ Single line position to be debugged

(n₁,*)  n₁ Initial line position
         * Last line of program

(*,n₂)   * First line of program
         n₂ Terminal line position

(*,*)    * First line of program
         * Last line of program

Line positions can be:

nnnnn     Statement label

Lnnnn     Source program line number as printed on the source listing by the FORTRAN Extended compiler (source listing line numbers change when debugging cards are interspersed in the program).

id.n      Alphanumeric UPDATE line identifier (refer to SCOPE Reference Manual); id must begin with an alphabetic character and contain no special characters.

A comma must be used to separate the line positions, and embedded blanks are not permitted. Any of the line position forms may be combined and bounds may overlap.
The AREA statement is used to specify an area to be debugged within a program unit. All debugging statements applicable to the program areas designated by the AREA statement must follow that statement. Each AREA statement cancels the preceding program AREA statement. An AREA statement (or contiguous set of AREA statements) specifies bounds for all debugging statements that occur between it and the next C$ DEBUG, AREA statement, or FORTRAN source statement.

AREA statements may appear only in an external or an internal debugging deck (figures 13-2, 13-3, and 13-4). If they are interspersed in a FORTRAN source deck, they will be ignored.

In an external debugging deck, the following form, with /name,/ specified, must be used. It can be used with both forms of the DEBUG statement.

```
C$  DEBUG

1    7
C$  AREA/name_1/bounds_1,...,bounds_n,...,/name_n/bounds_1,...,bounds_n
```

or

```
C$  DEBUG (name_1,...,name_n)

1    7
C$  AREA/name_1/bounds_1,...,bounds_n,...,/name_n/bounds_1,...,bounds_n
```

If /name,/ is omitted, or names in the /name,/ list do not appear in (name_1,...,name_n) in the DEBUG statement, the AREA statement is ignored.

In an internal debugging deck, the following form is used, and the bounds apply to the program unit that contains the deck.

```
C$  DEBUG

1    7
C$  AREA bounds_1,...,bounds_n
```
Example:

External deck

```c$
C$ DEBUG
C$ AREA /PROGA/(XNEW.10,XNEW.30),/SUB/*,L50)
C$ ARRAYS (TAB,TITLE,DAYS)
C$ AREA /SUB/(15,99)
C$ STORES (DAYS)
```

Internal deck

```c$
C$ DEBUG
C$ AREA (L10,*)
C$ FUNC5 (ABS)
```

**OFF STATEMENT**

```
C$ OFF
1 7 OFF(x_1,\ldots,x_n)
```

$x_1,\ldots,x_n$ debug options

The OFF statement deactivates the options specified by $x$, or all currently active options except NOGO, if no argument list exists. Only options activated by interspersed debugging statements are affected. Options activated in debug decks or by subsequent debugging statements are not affected.

The OFF statement is effective at compile time only. In a debugging deck, the OFF statement is ignored.
Example:

```
PROGRAM OFF (OUTPUT,DEBUG=OUTPUT)
C$ DEBUG
C$ STORES(C)
INTEGER A, B, C
5      C$ STORES(A, B, C)
      A = 1
      B = 2
      C = 3
10    *
      * MESSAGES WILL BE PRINTED FOR STORES INTO A, B, AND C.
      *
      C$ OFF
      *
15      A = 4
      B = 5
      C = 6
      *
      * THE OFF STATEMENT WILL ONLY AFFECT THE INTERSPERSED DEBUGGING
      * STATEMENT, SO THERE WILL BE NO MESSAGES FOR STORES INTO
      * A OR B. HOWEVER, C$ STORES(C) IN THE DEBUGGING DECK IS NOT
      * AFFECTED, AND A MESSAGE IS PRINTED FOR A STORE INTO C.
      *
      END
```

```
/DEBUG/ OFF AT LINE 7- THE NEW VALUE OF THE VARIABLE A IS 1
/DEBUG/ AT LINE 8- THE NEW VALUE OF THE VARIABLE B IS 2
/DEBUG/ AT LINE 9- THE NEW VALUE OF THE VARIABLE C IS 3
/DEBUG/ AT LINE 17- THE NEW VALUE OF THE VARIABLE C IS 6
```
PRINTING DEBUG OUTPUT

Debug messages produced by the object routines are written to a file named DEBUG. The file is always printed upon job termination, as it has a print disposition. To intersperse debugging information with output, the programmer should equate DEBUG to OUTPUT on the program card. An FET and buffer are supplied automatically at load time if the programmer does not declare the DEBUG file in the PROGRAM statement. For overlay jobs, the buffer and FET will be placed in the lowest level of overlay containing debugging. If this overlay level would be overwritten by a subsequent overlay load, the debug buffer will be cleared before it is overwritten.

At object time, printing is performed by seven debug routines coded in FORTRAN. These routines are called by code generated at compile time when debugging is selected.

<table>
<thead>
<tr>
<th>Routine</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUGARR</td>
<td>Checks array subscripts</td>
</tr>
<tr>
<td>BUGCLL</td>
<td>Prints messages when subroutines are called and when return to calling program occurs</td>
</tr>
<tr>
<td>BUGFUN</td>
<td>Prints messages when functions are called and when return to calling program occurs</td>
</tr>
<tr>
<td>BUGGTA</td>
<td>Prints a message if the target of an assigned GO TO is not in the list</td>
</tr>
<tr>
<td>BUGSTO</td>

</tr>
<tr>
<td>BUGTRC</td>
<td>Flow trace printing except for true sides of logical IF</td>
</tr>
<tr>
<td>BUGTRT</td>
<td>Flow trace printing for true sides of logical IF</td>
</tr>
</tbody>
</table>

STRACE

Traceback information from a current subroutine level back to the main level is available through a call to STRACE. STRACE is an entry point in the object routine BUGCLL. A program need not specify the D option on the FTN card to use the STRACE feature.

STRACE output is written on the file DEBUG; to obtain traceback information interspersed with the source program DEBUG should be equivalenced to OUTPUT in the PROGRAM statement.

PROGRAM MAIN

```plaintext
PROGRAM MAIN (OUTPUT,DEBUG-OUTPUT)
CALL SUB1
END
```
SUBROUTINE SUB1

SUBROUTINE SUB1
CALL SUB2
RETURN
END

SUBROUTINE SUB2

SUBROUTINE SUB2
I = FUNC1(2)
RETURN
END

FUNCTION FUNC1

FUNCTION FUNC1 (K)
FUNC1 = K ** 10
CALL STRACE
RETURN
END

Output from STRACE:

/DEBUG/ FUNC1 AT LINE 3 TRACE ROUTINE CALLED
          FUNC1 CALLED BY SUB2 AT LINE 2, FROM 1 LEVELS BACK
          SUB2 CALLED BY SUB1 AT LINE 2, FROM 2 LEVELS BACK
          SUB1 CALLED BY MAIN AT LINE 2, FROM 3 LEVELS BACK

A main program is at level 0; a subroutine or function called by the main program is at level 1; another
subprogram called by a subprogram is at level 2, etc. Calls are shown in order of ascending level number.
returns in order of descending level number.

For additional information regarding the debugging facility, refer to the FORTRAN Extended Debug
User’s Guide.
SYMBOLIC REFERENCE MAP

The reference map, which appears on a separate page following the source listing of the program, is a debugging aid useful for detecting errors which do not show up as compilation errors, such as, names which have been keypunched incorrectly. Program flow can be traced and the structure of the program examined.

The reference map is a list of programmer created symbols in a program unit. Names of symbols generated by the compiler (such as library routines called for input/output) do not appear. Names are listed alphabetically within the following classes:

Entry points, variables, file names, external references, inline functions, NAMELIST group names, statement and FORMAT statement numbers, DO loops, common blocks, equivalence classes.

The programmer may select from three types of reference map or suppress the map completely. The type of map produced is determined by the R option on the FTN control card.

R = 0    No map
R = 1    Short map (symbols, addresses, properties)
R = 2    Long map (symbols, addresses, properties, references by line number, and DO loop map)
R = 3    Long map and printout of common block members and equivalence classes

If no selection is made, the default option is R = 1. However, if the control card option L, which suppresses output, equals 0; no map is produced.

Field length should be increased by 1000 octal if the long map is specified; if it is too short, one of the following error messages is printed:

CANT SORT THE SYMBOL TABLE   INCREASE FL BY nnnB
REFERENCES AFTER LINE nnn LOST   INCREASE FL BY nnnB

Fatal errors in the source program cause certain parts of the map to be suppressed, incomplete, or inaccurate. The DO loop map is suppressed, and assigned addresses are different when fatal execution or compilation errors occur. References are not accumulated for statements containing syntax errors.
The number of references that can be accumulated and sorted for the reference map is eight times the number of symbols in the source program if the field length is 50000 octal. For example, in a source program containing 1000 (decimal) symbols, with a field length of 50000 octal, approximately 8000 (decimal) references can be accumulated.

Although formats for portions of the reference map differ, they all contain the following information:

- The symbol as it appears in the FORTRAN program
- Properties associated with the symbol
- List of references to the symbol; line numbers in the list refer to the first line of the statement. Multiple references on a line are printed as n*k where n is the number of references and k is the line number.

**CLASSES**

**ENTRY POINTS**

Entry point symbols include subprogram names and names appearing in ENTRY statements; they are printed in the reference map under the headings: ENTRY POINTS, DEF LINE, REFERENCES.

- **ENTRY POINTS**
  - Entry point name as it appears in the source program, and the program relative address.

- **DEF LINE**
  - Line number of subprogram statement on which entry point is defined.

- **REFERENCES**
  - Line number at which entry point is referenced (none for main program). RETURN statements constitute a reference to an entry point. References to a function value, in a function subprogram, appear in the variable map.

```fortran
SUBROUTINE IOTA (A, M)
  C IOTA PUTS CONSECUTIVE INTEGERS STARTING AT 1 IN EVERY ELEMENT OF
  C THE ARRAY A
  DIMENSION A(M)
  DO1 I = 1, M
    1 A(I) = I
  RETURN
END
```

**ENTRY POINTS**

<table>

</tr>
</tbody>
</table>

I-14-2

60305600 A
### VARIABLES

Variable symbols include variables and arrays (including those in common), dummy arguments, RETURNS names, and for a function subprogram, the function name when it is used as a variable.

<table>
<thead>
<tr>
<th>VARIABLES</th>
<th>SN</th>
<th>TYPE</th>
<th>RELOCATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>O</td>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>Y</td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>Properties</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>*UNDEF</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**VARIABLES**

Object program or common relative address; 0 for dummy arguments, and variable name as it appears in source program.

**SN**

Stray name flag. Variable names which appear only once in a subprogram are indicated by * . They are classified as stray, since they may be keypunch errors, misspellings, etc. A legal usage that would cause a name to be called stray is a DO loop in which the control variable is not referenced. (DO loops are mapped for $R = 2$ and $R = 3$ only.)

**TYPE**

Type of variable (logical, integer, real, double precision, complex). RETURNS is printed for RETURNS dummy arguments.

**RELOCATION**

Subdivided into properties, blockname, and references.

**Properties**

The keywords UNDEF, ARRAY, UNUSED may be printed in this column.

***UNDEF**

Symbol has not been defined. Variables used before definition are not listed as undefined. For reference map purposes, a symbol is considered to be defined if any of the following conditions hold:

- It appears in a COMMON or DATA statement.
It is a member of an equivalence group other than the base member (The base member of an equivalence group is the member with the smallest address. In an array X(10), X(1) has the smallest object program address, X(10) the largest.) An undefined non-base member is not detected by the compiler.

It is a simple variable or array element on the left-hand side of an assignment statement.

It appears in an ASSIGN statement.

It is the control variable in a DO loop.

It is a simple variable or array element which appears as an argument in a subroutine or function call.

It appears in an input/output list.

It is a dummy argument.

ARRAY

*UNUSED

Blockname

blank

F.P.

/

name

References

REFS

Symbol is an array name.

Symbol is an unused dummy argument. If no further information appears on the line and it is not a RETURNS argument, it is a simple variable.

Symbol is not in common; address is relative to program unit.

Dummy argument.

Symbol is in blank common; address is relative to blank common.

Name of labeled common block where symbol appears.

Number of times variable names appear in specification or assignment statements.
DEFINED

Number of times names are defined. Definitions are listed for names appearing in DATA statements, control variables of DO loops, names defined in an ASSIGN or assignment statement, and names defined by READ or ENCODE/DECODE statements. Dummy arguments are defined in the subprogram header line.

I/O REFS

Input/output references are collected for symbols used as variable file names in input/output statements.

References to the function name in a function subprogram are listed in the VARIABLE map rather than the EXTERNALS map.

References are collected after statement functions are expanded; they are not collected for the arguments before the expansion.

Example:

If ASF(J)=(J+1)/(J-1) is a statement function and K=ASF(I) is on line 5; two references will be listed for I on line 5.

Example:

```
FUNCTION AVG(J)
  C AVG COMPUTES THE AVERAGE OF THE FIRST J ELEMENTS OF COMMON.
  COMMON A(100)
  AVG=0.
  DO 1 I = 1, J
     1 AVG=AVG+A(I)
  AVG=AVG/FLOAT(J)
  RETURN
END
```

SYMBOLIC REFERENCE MAP (R=1)

60305600 A
FILE NAMES

File names include those used as logical file names (unit number) in the input/output statements or names declared as files on the PROGRAM statement in a main program. They are printed in the reference map under the following headings: FILE, NAME, MODE.

FILE
Object program relative address of the file information table (FIT)

NAME
Name of file

MODE
Type of input/output operations performed. They may be formatted (FMT), unformatted (UNFMT), buffered (BUF), or MIXED (combination of FMT, UNFMT, BUF).

References are divided into categories:

READS
Input operations

WRITES
Output operations

MOTION
Positioning operations; rewind, backspace, and ENDFILE

PROGRAM VARDIM2 (OUTPUT, TAPE6=OUTPUT, DEBUG=OUTPUT)

I-14-6

60305600 A
EXTERNAL REFERENCES

External references include names of subroutines or functions external to a program unit. If the T or D option is specified on the FTN control card, intrinsic functions are compiled as external references. Library functions appear as external references when T or D is specified, as they are called by name. Names of system routines not explicitly called in the source program, such as those used for input/output and exponentiation, are suppressed.

External references are printed in the reference map under the following headings: EXTERNALS, TYPE, ARGS.

EXTERNALS  Symbol as it appears in source program.

TYPE

blank  Subroutine

NO TYPE  Conversion follows the same rule as for octal or Hollerith data

other  Real, integer, double precision, complex, logical

ARGS  Number of arguments used to reference the external symbol, followed by:

blank  Programmer defined function or subroutine

F.P  Dummy argument

LIBRARY  Call by value library function

The line numbers on which symbol was referenced appear as the last item.

Example:

EXTERNALS  TYPE  ARGS

AVG  0  INC  3

IOTA  2  MULT  0

PVAL  REAL  2

INLINE FUNCTIONS

Inline functions include names of intrinsic and statement functions appearing in the subprogram. They are printed under the following headings: INLINE FUNCTIONS, TYPE, ARGS, INTRIN, SF, LINE, REFERENCES.

INLINE FUNCTIONS  TYPE  ARGS

PVALSF  REAL  2  SF
INLINE FUNCTIONS  Symbol name as it appears in the listing

TYPE  Arithmetic type, NO TYPE means no conversion is performed in mixed mode expressions

ARGS  Number of arguments with which the function is referenced

INTRIN  Intrinsic function

SF  Statement function

LINE  Blank for intrinsic functions; definition line for statement functions

REFERENCES  Lines on which function is referenced

**NAMELIST GROUP NAMES**

The NAMELIST group name, line on which it was defined, and all references to the name are included in this class. If NAMELIST names were not used, this portion of the reference map is suppressed.

Example:

<table>
<thead>
<tr>
<th>NAMELISTS</th>
<th>DEF LINE</th>
<th>REFERENCES</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAMPLE</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>TEST</td>
<td>2</td>
<td>7</td>
</tr>
</tbody>
</table>

The group name SAMPLE was defined on line 2 and referenced on lines 3,6,10 and 11. The group name TEST was defined on line 2 and referenced on lines 7 and 9.
STATEMENT AND FORMAT LABELS

STATEMENT LABELS

Relative address of statement, followed by statement number. Inactive labels are printed with a zero address. A label becomes inactive when the compiler has deleted all references to it through optimization.

The following example contains the only reference to label 5 in a program. The label is inactive because the compiler deletes jumps to the next statement.

```
IF(X)10,5,10
  5 X=1
  10 CONTINUE
```

Inactive labels and DO loop terminators are listed as INACTIVE with a zero address.

The type and activity are listed after the statement number:

<table>

</table>
DO LOOP MAPS

This map, generated by the R = 2 or R = 3 option, is a printout of all DO loops in the source program and their properties. Loops are listed in order of appearance in the program.

### Subroutine SET (A,M,V)

C
SET PUTS THE VALUE V INTO EVERY ELEMENT OF THE ARRAY A
DIMENSION A(M)
DO1 1  I = 1,M
 1 A(I) = 0.0
C
ENTRY INC
C
INC ADDS THE VALUE V TO EVERY ELEMENT IN THE ARRAY A
DO 2  I = 1,M
 2 A(I) = A(I) + V
RETURN
END

---

</tbody>
</table>

If loop is not fully optimized by the compiler, the reasons are listed:

| **EXT REFS** | Loop contains references to an external subroutine or function, or it is an input/output loop. |
| **ENTRIES** | Loop is entered from outside its range. |
**EXITS**
Loop contains references to labels outside its range.

**NOT INNER**
Loop is not loop innermost in a nest.

### COMMON BLOCKS

Common block symbols include common block names, and names declared in COMMON statements to be variables and arrays in common.

<table>
<thead>
<tr>
<th>COMMON BLOCKS</th>
<th>LENGTH</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON BLOCKS</td>
<td>Block name</td>
<td></td>
</tr>
<tr>
<td>LENGTH</td>
<td>Total block length</td>
<td></td>
</tr>
</tbody>
</table>

When R = 1 or R = 2 is specified, only the above information is listed. When R = 3, the following details appear for each member declared in a COMMON statement.

<table>
<thead>
<tr>
<th>MEMBERS</th>
<th>Relative address (distance from origin of common block)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIAS NAME</td>
<td>Name of member of common block</td>
</tr>
<tr>
<td>(LENGTH)</td>
<td>Number of words allocated for member</td>
</tr>
</tbody>
</table>

If an equivalence class is linked to common, all members of the equivalence group become members of the common block. They are listed in the equivalence class printout.

<table>
<thead>
<tr>
<th>COMMON BLOCKS</th>
<th>LENGTH</th>
<th>MEMBERS - BIAS NAME(LENGTH)</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON BLOCKS</td>
<td>Length</td>
<td>12</td>
</tr>
</tbody>
</table>

### EQUIVALENCE CLASSES

Equivalence symbols appear only when R = 3 is specified. All members of an equivalence group are listed. Any symbols added through linkage to common are not included.

```
PROGRAM GOME (OUTPUT, TAPE=OUTPUT)
COMMON A(1), B, C, D, F, G, H
INTEGER A, B, C, D, E(3,4), F, H
EQUIVALENCE (A, E, I)
NAMELIST/VLIST/A, B, C, D, E, F, G, H, I

DO 1 J = 1, 12
  A(J) = J
1 WRITE (6, VLIST)
STOP
END
```

<table>
<thead>
<tr>
<th>EQUIV CLASSES</th>
<th>LENGTH</th>
<th>MEMBERS - BIAS NAME(LENGTH)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A</td>
<td>12</td>
</tr>
</tbody>
</table>

I-14-12
**EQUIV**

*ERROR* Class is in error (more than one member of an equivalence group is in common, or common block origin is extended by EQUIVALENCE statement or conflicting equivalencing attempted).

<table>
<thead>
<tr>
<th>BASE MEMBER</th>
<th>Class is in common</th>
</tr>
</thead>
<tbody>
<tr>
<td>blank</td>
<td>Other</td>
</tr>
</tbody>
</table>

**CLASSES**

If the equivalence group is not in common, the first member of the group (the member with the smallest object code address) is printed. If the group is in common, the name of the symbol in common which linked the equivalence group to the common block is printed. When an equivalence group is in common, the base member of the equivalence group is the first member of the common block.

**MEMBERS**

Equivalence group length

**BIAS**

Distance between an equivalence group member and the first member of the group. In an equivalence group A.B.C(10), C(1) is the base member, C(2) has a bias of 1, C(3) has a bias of 2, A and B have a bias of 9.

**NAME**

Name of equivalence group member

**LENGTH**

Number of words allocated for the member

Members of an equivalence group are printed in order of increasing bias. If the class is in error, the numbers associated with the class length and bias are meaningless.
PROGRAM STATISTICS

At the end of the reference map, program statistics are printed in octal and decimal.

<table>
<thead>
<tr>
<th>STATISTICS</th>
<th>Octal</th>
<th>Decimal</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM LENGTH</td>
<td>145B</td>
<td>101</td>
</tr>
<tr>
<td>BUFFER LENGTH</td>
<td>2033B</td>
<td>1051</td>
</tr>
<tr>
<td>BLANK COMMON</td>
<td>14B</td>
<td>12</td>
</tr>
</tbody>
</table>

- **PROGRAM LENGTH**: Program length including executable code, storage for variables not in common, constants, temporaries, etc., but excluding buffers and common blocks.
- **BUFFER LENGTH**: Total space occupied by input/output buffers and FITs
- **COMMON LENGTH**: Total common length, excluding blank common
- **BLANK COMMON**: Length of blank common

DEBUGGING (USING REFERENCE MAP)

NEW PROGRAM

The reference map can be used to find incorrectly punched names as well as other items that will not appear as compilation errors. The basic technique consists of using the compiler as a verifier and correcting the fatal errors until the program compiles. Using the listing, the R = 3 reference map, and the original flowcharts, the following information should be checked by the programmer:

Names incorrectly punched
Stray name flag in the variable map
Functions that should be arrays (undeclared arrays)
Functions that should be in line instead of external
Variables or functions with incorrect type
Unreferenced format statements
Unused dummy arguments
Ordering of members in common blocks
Equivalence classes

60305600 A
EXISTING PROGRAM

The reference map can be used to understand the structure of an existing program. Questions concerning the loop structure, external references, common blocks, arrays, equivalence classes, input/output operations, and so forth, can be answered by checking the reference map.
PROGRAM OUT

Program OUT illustrates the WRITE and PRINT statements.

Features:

Control cards
WRITE and PRINT statements
Carriage control
PROGRAM statement

PAT,T10,CM45000.

The job card must precede every job run under the SCOPE operating system. PAT is the job name. T10 specifies a maximum of 10 (octal) seconds central processor time, and CM45000 requests 45000 (octal) words of memory for the job.

FTN.

Specifies the FORTRAN Extended compiler and uses the default parameters. (section 11, part 1.)

LGO.

The binary object code is loaded and executed.

If no alternative files are specified on the FTN card, the FORTRAN Extended compiler reads from the file INPUT and outputs to two files: OUTPUT and LGO. Listings, diagnostics, and maps are output to OUTPUT and the relocatable object code to LGO.

7/8/9

The end-of-record card (EOR) or end-of-section card (EOS) separates control cards from the remainder of the INPUT file. The end-of-record card is a multipunch 7/8/9 in column 1; it must follow the SCOPE control cards in every job.
PROGRAM OUT (OUTPUT, TAPE6=OUTPUT)

The PROGRAM card identifies this as the main program with the name OUTPUT and specifies the file OUTPUT. Output unit 6 will be referenced in the program. All files used by a program must be specified in the PROGRAM card of the main program.

TAPE6=OUTPUT is included because output unit 6 is referenced in a WRITE statement. The unit number must be preceded by the letters TAPE. All data written to unit 6 will be placed in the SCOPE file OUTPUT and output to the printer.

WRITE (6, 200) INK

The WRITE statement outputs the variable INK to output unit 6. If a PRINT statement had been used instead of WRITE:

PRINT 200, INK

TAPE6=OUTPUT would not be needed in the PROGRAM card; PROGRAM OUT (OUTPUT) would be sufficient.

100 FORMAT (*1 THIS WILL PRINT AT THE TOP OF A PAGE*)

This FORMAT statement uses * * to delimit the literal. 1 is a carriage control character which causes the line to be printed at the top of a page.

200 FORMAT (I5, * = INK OUTPUT BY WRITE STATEMENT*)

Although the variable INK is 4 digits, a specification of I5 is given because the first character is always interpreted as a control. In this case, the carriage control character is a blank and output will appear on the next line.

6/7/8/9

This is the end of file (EOF) or end of partition card; a multipunch 6/7/8/9 in column 1. This card must appear as the last card in each SCOPE job.
```
7/8/9 in column 1

PROGRAM OUT (OUTPUT, TAPE 6=OUTPUT)
PRINT 100
100 FORMAT (*1 THIS WILL PRINT AT THE TOP OF A PAGE*)
     INK = 2000+4000
     WRITE (6,200) INK
200 FORMAT (I5, *= INK OUTPUT BY WRITE STATEMENT*)
     PRINT 300, INK
300 FORMAT (1H *I4*30H = OUTPUT FROM PRINT STATEMENT)
     STOP
     END
```

Output:

```
THIS WILL PRINT AT THE TOP OF A PAGE
6000 = INK OUTPUT BY WRITE STATEMENT
6000 = OUTPUT FROM PRINT STATEMENT
```
PROGRAM B

Program B generates a table of 64 characters indicating which character set is being used. The internal bit configuration of any character can be determined by its position in the table. Each character occupies six consecutive bits.

Features:

- Simple DO loop
- FORMAT with H.,I,X and A elements

The print statement PRINT1 has no input/output list; it prints out the heading at the top of the page using the information provided by the FORMAT statement on line 3. 25H specifies a Hollerith field of 25 characters, 1 is the carriage control character, and the two slashes // cause one line to be skipped before the next Hollerith field is printed. The slash at the end of the FORMAT specification skips another line before the program output is printed.

```
DO 3 I=1,8
J=I-1
```

These statements output numbers 0 through 7. A DO index cannot begin with a zero.
PRINT 2, J, NCHAR

Prints out 0 through 7 (the value of J) on the left and the 8 characters in NCHAR on the right. The first iteration of the DO loop prints NCHAR as it appears on line 4. The octal value 01 is a display code A, 02 is a B, 03 is a C, etc.

NCHAR=NCHAR+10 10 10 10 10 10 10 00 00B

The octal constant 1010101010101010000B is added to NCHAR, and when this is printed on the second iteration of the DO loop, the octal value 10 is printed as a display code H, 11 as I, 12 as J, etc. Compare these values with the Character Set in Section 1, Part 3.

BBBBB+T10+CM70000+P15*
MAP(OFF)
FTN*
LGO*
7/8/9 in column 1

    PROGRAM B (OUTPUT)
    PRINT 1
       1 FORMAT(25H1TABLE OF INTERNAL VALUES//12H 01234567,/)  
       NCHAR = 00 01 02 03 04 05 06 07 00 00B
       DO 3 I = 1,8
          J=I-1
       PRINT 2, J,NCHAR
       2 FORMAT(I3,1X,A8)
       NCHAR=NCHAR+10 10 10 10 10 10 10 00 00B
       STOP
       END
    6/7/8/9 in column 1

Output:

    0 ABCDEFG
    1 HIJKLMNO
    2 PQRSUVWM
    3 XYZ01234
    4 56789+-*
    5 /( )= ,.
    6 $[ ]##..+
    7 ++<<>=^&**
PROGRAM MASK

Program MASK reads names and home states from data cards ignoring all but the first two letters of the state name. If the state name starts with the letters CA, the name is printed.

Feature:

Masking

1 FORMAT (1H1,5X,4HNAME,///)
   PRINT 1

The printer is directed to start a new page, print the heading NAME, and skip 3 lines.

3 READ 2,LNAME,FNAME,ISTATE,KSTOP
   IF(KSTOP.EQ.1) STOP

The last name is read into LNAME, first name into FNAME, and home state into ISTATE. The last card in the deck contains a one which will be read into KSTOP as a stop indicator. The IF statement on line 6 tests for the stop indicator.

IF((ISTATE.AND.777700000000000000000000).NE.(2HCA.AND.7777000000000000
K000000) ) GO TO 3

The relational operator .NE. tests to determine if the first two letters read from the data card into variable ISTATE match the two letters of the Hollerith constant CA. The last eight characters (48 bits) in ISTATE are masked and the two remaining characters are compared with the word containing the Hollerith constant CA, also similarly masked. If the bit string forming one word is not identical to the bit string forming the other word, ISTATE is not equal to CA and the IF statement test is true.

The bit configuration of CALIFORNIA, the Hollerith constant CA and the mask follows:

<table>
<thead>
<tr>
<th>Hollerith</th>
<th>C</th>
<th>A</th>
<th>L</th>
<th>I</th>
<th>F</th>
<th>O</th>
<th>R</th>
<th>N</th>
<th>I</th>
<th>A</th>

<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
</tr>
</tbody>
</table>

When the masking expression (ISTATE.AND.7777000000000000000B) is completed, the first two characters of CALIFORNIA remain the same and last eight characters are zeroed out. The AND operation follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>000011</th>
<th>000001</th>
<th>001100</th>
<th>001001</th>
<th>000110</th>
<th>001111</th>
<th>010010</th>
<th>001110</th>
<th>001001</th>
<th>000001</th>
</tr>
</thead>
<tbody>
<tr>
<td>Octal</td>
<td>111111</td>
<td>111111</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
<td>000000</td>
</tr>
</tbody>
</table>

| Bit | 000011| 000001| 000000| 000000| 000000| 000000| 000000| 000000| 000000| 000000 |

When (2HCA.AND.77770000000000000000B) is evaluated, the same result is obtained. Thus, in both words, all bits but those forming the first two characters will be masked, making a valid basis for comparing the first two characters of both words. If the result of the mask is true, the last name and first name are printed (statement 10), otherwise the next card is read.

PROGRAM EQUIV

Program EQUIV places values in variables that have been equivalenced and prints these values using the NAMELIST statement.

Features:

EQUIVALENCE statement

NAMELIST statement

EQUIVALENCE (X,Y), (Z,I)

Two real variables X and Y are equivalenced; the two variables share the same location in storage, which can be referred to as either X or Y. Any change made to one variable changes the value of the others in an equivalence group as illustrated by the output of the WRITE statement, in which both X and Y have the value 2. The storage location shared by X and Y contained first 1. (X=1.) then 2. (Y=2.).

The real variable Z and the integer variable I are equivalenced, and the same location can be referred to as either real or integer. Since integer and real internal formats differ, however, the output values will not be the same.

For example, the storage location shared by Z and I contained first 3, then the integer value 4. When I is output, no problem arises; an integer value is referred to by an integer variable name. However, when this same integer value is referred to by a real variable name, the value 0.0 is output. The internal format of real and integer values differ.

Although they can be referred to by names of different types, the internal bit configuration does not change. An integer value output as a real variable does not have an exponent and its value will be small.

When variables of different types are equivalenced, the value in the storage location must agree with the type of the variable name; or unexpected results may be obtained.
WRITE(6,OUTPUT)

This NAMELIST WRITE statement outputs both the name and the value of each member of the NAMELIST group OUTPUT defined in the statement NAMELIST/OUTPUT/X,Y,Z,I. The NAMELIST group is preceded by the group name, OUTPUT, and terminated by the characters SEND.

PROGRAM EQUIV (OUTPUT,TAPE6=OUTPUT)
EQUIVALENCE (X,Y),(Z,I)
NAMELIST/OUTPUT/X,Y,Z,I
X=1.
Y=2.
Z=3.
I=4
WRITE(6,OUTPUT)

Output:

$OUTPUT
X = 0.2E+01,
Y = 0.2E+01,
Z = 0.0,
I = 4,
$END
PROGRAM COME

Program COME places variables and arrays in common and declares another variable and array equivalent to the first element in common. It places the numbers 1 through 12 in each element of the array A and outputs values in common using the NAMELIST statement.

Features:

COMMON and EQUIVALENCE statements
NAMELIST statement

COMMON A(1), B, C, D, F, G, H

Variables are stored in common in the order of appearance in the COMMON statement A(1),B,C,D,F,G,H. Variables can be dimensioned in the COMMON statement; and in this instance, A is dimensioned so that it can be subscripted later in the program. If A were not dimensioned, it could not be used as an array in statement 1.

INTEGER A, B, C, D, E(3,4), F, H

All variables with the exception of G are declared integer. G is implicitly typed real.

EQUIVALENCE(A, E, I)

The EQUIVALENCE statement assigns the first element of the arrays A and E and an integer variable I to the same storage location. Since A is in common, E and I will be in common. Variables and array elements are assigned storage as follows:

<table>
<thead>
<tr>
<th>Relative Address</th>

</table>
DO 1 J=1,12
1 A(J)=J

The DO loop places values 1 through 12 in array A. The first element of array A shares the same storage location with the first element of array E. Since B is equivalent to E(2,1), A(2) is equivalent to B, A(3) to C, A(4) to D, etc.

Any change made to one member of an equivalence group changes the value of all members of the group. When 1 is stored in A, both E(1,1) and I have the value 1. When 2 is stored in A(2), B and E(2,1) have the value 2. Although B and E(2,1) are not explicitly equivalenced to A(2), equivalence is implied by their position in common.

The implied equivalence between the array elements and variables is illustrated by the output.

The NAMELIST statement is used for output. A NAMELIST group, V, containing the variables and arrays A,B,C,D,E,F,G,H,I is defined. The NAMELIST WRITE statement, WRITE(6,V), outputs all the members of the group in the order of appearance in the NAMELIST statement. Array E is output on one line in the order in which it is stored in memory. There is no indication of the number of rows and columns (3,4).

G is equivalent to E(3,2) and yet the output for E(3,2) is 6 and G 0.0. G is type real and E is type integer. When two names of different types are used for the same element, their values will differ because the internal bit configuration for type real and type integer differ (refer to Program EQUIV).

PROGRAM COME (OUTPUT, TAPE6=OUTPUT)
COMMON A(1),B,C,D, F,G,H
INTEGER A,B,C,D,E(3,4),F, H
EQUIVALENCE (A,E,I)
NAMELIST/V/A,B,C,D,E,F,G,H,I

DO 1 J = 1, 12
1 A(J)=J

WRITE (6,V)
STOP
END
Output:

```plaintext
$V
A = 1,
B = 2,
C = 3,
D = 4,
E = 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12,
F = 5,
G = 0.0,
H = 7,
I = 1,
$END
```
PROGRAM LIBS

Program LIBS illustrates library subroutines provided by FORTRAN Extended.

Features:

EXTERNAL used to pass a library subroutine name as a parameter to another library routine.

Division by zero.

LEGVAR used to test for overflow or divide error conditions.

Library functions used:

   LOCF
   LEGVAR

Library subroutines used:

   DATE
   TIME
   SECOND
   RANGET

DATE is a library subroutine which returns the date entered by the operator from the console. DATE is declared external because it is used as a parameter to the function LOCF. Declaring DATE external does not prevent its use as a library subroutine in this program.

PRINT2,TODAY,CLOCK
2 FORMAT(’TODAY=’Y, A10, ’, CLOCK=’,A10)

These statements print the date and time. The leading and trailing blanks appear with the 10 alphanumeric characters returned by the subroutine DATE because the operator typed in the date this way. However, since he may choose to use a 4-digit year, it may be prudent to use A11 in the output FORMAT specification to guarantee at least one leading space. The value returned by TIME is changed by the system once a second, and the position of the digits remain fixed; a leading blank always will appear. The format of DATE and TIME can be checked by observing any listing, as the routines DATE and TIME are used by the compiler to print out the date and time at the top of compiler output listings.
CALL SECOND(TYME)

When SECOND is called, the variable name TYME is used. A variable name cannot be spelled the same as a program unit name. If Program LIBS had not called the subroutine TIME, a variable name could be spelled TIME.

LOCN-LOCF(DATE)

DATE is not a variable name as it appears in an EXTERNAL statement.

Library function LOCF returns the address of DATE.

CALL RANGT(SEED)

Library subroutine RANGT returns the seed used by the random number generator RANF if it is called. If RANGT is called after RANF has been used, RANGT will return the value currently being processed by the random number generator. With the library subroutine RANSET, this same value could be used to initialize the random number generator at a later date.

PRINT3, TYME, LOCATN, LOCATN, SEED, SEED
3 FORMAT('THE ELAPSED CPU TIME IS',G14.5,' SECONDS.'//'LOCATION OF
1 DATE ROUTINE IS',F015.15,' OR',F17.17,' IN DECIMAL.'//'THE INITIAL VALUE
2 OF THE RANF SEED IS',F022.15,' OR',F17.15,' IN G30.15 FORMAT.')

These statements print out the values returned by the routines SECOND, LOCF, and RANGT.

Asterisks are used to delineate Hollerith fields in the format specification to illustrate the point that excessive use of asterisks can be extremely difficult to follow.

Y=0.0
WOM-7.2/Y
IF(0.NE. LEGVAR(WOW))PRINT4,WOW

These statements illustrate the use of the library function LEGVAR within an IF statement to test the validity of division by zero. LEGVAR checks the variable WOW. This function returns a result of -1 if the variable is indefinite, +1 if it is out of range, and 0 if it is normal. Comparing the value returned by LEGVAR with 0 shows that the number is either indefinite or out of range. The output RRR shows the variable is out of range. Division by zero is allowed on the 6000/7000 and CYBER 70 series computers and there is a representation for an infinite value (refer to section 4, part 3).

The line of '*-* on the output is produced by the FORMAT specification in statement number 4 50(2H*-).
PROGRAM LIBS (OUTPUT)

EXTERNAL DATE

CALL DATE (TODAY)
CALL TIME (CLOCK)

PRINT 2, TODAY, CLOCK
2 FORMAT(*1TODAY=*AU, *CLOCK=*AU)

CALL SECOND(TYME)
LOCATN=LOCF(DATE)
CALL RANGET(SEED)

4 FORMAT(1H0.50(2H-))/DIVIDE ERROR, WOW PRINTS AS=*G10.2"
END
PROGRAM PIE

Program PIE calculates an approximation of the value of $\pi$.

Feature:

Library function RANF

The random number generator, RANF, is called twice during each iteration of the DO loop, and the values obtained are stored in the variables X and Y.

```
DATA CIRCLE, DUD/2*0.0/
```

The DATA statement initializes the variables CIRCLE and DUD with the value 0.0.

Each time the DO loop is iterated, a random number, uniformly distributed over the range 0-1, is returned by the library function RANF, and this value is stored in the variable X. The value of X will be $0 \leq X < 1$. DUD is a dummy argument which must be used when RANF is called.

```
Y = RANF(DUD)
```

RANF is referenced again; this time to obtain a value for Y.

```
IF(X*X+Y*Y.LE.1.) CIRCLE = CIRCLE + 1.
```

The IF statement and the arithmetic expression $4.0^*CIRCLE/10000$, calculate an approximation of the value of $\pi$. The value of $\pi$ is calculated using Monte Carlo techniques. The IF statement counts those points whose distance from CIRCLE(0,0) is less than one. The ratio of the number of points within the quarter circle to the total number of points approximates $1/4$ of $\pi$. The value PI is printed by the NAMELIST statement WRITE(6,OUT)
PROGRAM PIE (OUTPUT, TAPE6=OUTPUT)
DATA CIRCLE, DUD = 2*0.0
NAMELIST/OUT/PI

DO 1 I = 1, 10000
  X = RANF (DUD)
  Y = RANF (DUD)
  IF (X*X+Y*Y .LE. 1.) CIRCLE = CIRCLE + 1.
1 CONTINUE
PI = 4.*CIRCLE/10000.
WRITE (6, OUT)

STOP
END

Output:

$OUT
PI = 0.31596E+01,
$END
PROGRAM ADD

Program ADD illustrates the use of the DECODE statement.

Features:

DECODE statement.

ENCODEx and DECODE

ENCODEx and DECODE are simpler to understand when related to the WRITE and READ statements.

DECODE (READ)

A READ statement places the image of each card read into an input buffer. The card image occupies eight computer words, each word containing ten display code characters. Compiler routines convert the character string in the card image into floating point, integer or logical values, as specified by the FORMAT statement, and store these values into the locations associated with the variables named in the list.

With DECODE, the information in the input buffer comes from the array specified in the DECODE statement. The number of words moved to the input buffer from the array is determined by the record length. Since the input buffer is 150 words long, the maximum record length is 150.

With the READ statement, when the FORMAT specification indicates a new record is to be processed (by a / or the final right parenthesis of the FORMAT statement) a new record is obtained by reading another card into the input buffer.

With the DECODE statement, when the FORMAT statement indicates a new record is to be processed (/ or final right parenthesis), as many words as indicated by the record length are obtained from the array and placed in the input buffer.

ENCODEx (WRITE)

A WRITE statement causes the output buffer to be cleared to 150 spaces. Data in the WRITE statement list is converted by compiler routines into a character string according to the format specified in the FORMAT statement, and placed in the output buffer. When the FORMAT statement indicates an end of a record with either a / or the final right parenthesis, the character string is passed from the output buffer to the SCOPE output system; the output buffer area is reset to spaces, and the next string of characters is placed in the buffer.

The ENCODEx statement is processed by compiler routines in the same way as the WRITE statement; but when a record is output, the character string is placed into the array specified within the parentheses of the ENCODEx statement. The number of words moved from the output buffer to the array is determined by the record length.
The number of computer words in each ENCODE or DECODE record is determined by dividing the record length by 10 and rounding up. For example, a record length of 33 requires 4 words, and a record length of 71 requires 8 words.

As a mnemonic aid, it may be useful to remember READ ends with a D and corresponds to DECODE, WRITE ends with an E and corresponds to ENCODE.

In the following program, the format of data on card input is unknown, but column 1 is a key to the type of data. The complete record is read under A format, and a test is made on column 1 to determine the type of data. If column 1 contains a 2, a set of numbers is to be summed and printed out. Using the DECODE statement, these numbers are converted from A format to I format and written in the list variables, INK. The values in the array INK are added and stored in ITOT.

```
PROGRAM ADD (INPUT,CUTPUT,TAPE5=INPUT,TAPE6=OUTPUT)
DIMENSION CARD (8), INK (77)
  2 READ (5,100) KEY1,CARD
100 FORMAT (I1,?A10,A9)
   IF (EOF(5)) 80,90
90 IF (KEY1-2) 3,8,3
  3 CALL ERROR1
  8 GO TO 2
  3 WRITE (6,300) CARD
300 FORMAT (1H1,?A10,A7//)
  DECODE (77,17,CARD) INK
  17 FORMAT (77I1)
   ITOT = 0
   DO 4 I = 1,77
   4 ITOT = ITOT + INK(I)
   ISAVE = ITOT
   WRITE (6,200) ISAVE
200 FORMAT (19X,*TOTAL OF 77 SCORES ON CARD = *,I10)
  80 STOF
END

SUBROUTINE ERROR1
WRITE (6,1)
  1 FORMAT (5X,*NUMBER IS NOT 2*)
RETURN
END
```
Output:

235368996321452135468796321456879632145369874512369582121452563214587963214

TOTAL OF 77 SCORES ON CARD = 342

DIMENSION CARD(8), INK(77)

CARD is dimensioned 8 to receive card input.

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>23536899632145213546879632145687963214536987451236958212145256321458794321400000</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

INK is dimensioned 77. As each character from the card is decoded, it will become an element of the array INK.

2  READ(5,100)KEY1,CARD
100  FORMAT(I1,7A10,A9)

The first column of the card, which is known to be integer, is read into KEY1 under I format. The remaining 77 characters and 2 blanks are read into the array CARD under A format, as the type of input is unknown.

IF (EOF(5)) 80,90

A test is made for end of file. If the last card has been read, the program terminates. If not, the first digit on the card is tested for 2 (statement 90); and if it is 2, the array CARD is printed (statement 8). An error routine is called if the first digit on the card is not 2.

DECODE (77,17,CARD) INK

The data on the input card is decoded. 77 characters in the array CARD are read into the array INK under I format; they are converted from alphanumeric format to integer format.

DO 4 I=1,77
4  ITOT=ITOT+INK(I)

The DO loop totals the elements of the array INK (the 77 numbers on the card).

WRITE(6,200)ISAVE
200  FORMAT(19X,'TOTAL OF 17 SCORES ON CARD = ',I10)

Prints the total and a heading.
PROGRAM PASCAL

Program PASCAL produces a table of binary coefficients (Pascal’s triangle).

Features:

Nested DO loops
DATA statement
Implied DO loop

INTEGER L(11)

L is defined as an 11-element integer array.

DATA L(11)/1/

The DATA statement stores the value 1 in the last element of the array L. When the program is executed L(11) has the initial value 1.

PRINT 4,(I,I=1,11)

This statement prints the headings. The implied DO loop generates the values 1 through 11 for the column headings.

PRINT 3,(L(J),J=K,11)

This is a more complicated example of an implied DO loop. The index value J is used as a subscript instead of being printed. The end of the array is printed from a variable starting position. The 1, which appears on the diagonal in the output is not moving in the array; it is always in L(11); but the starting point is moving.

DO 2 I=1,10
   K=11-I

These statements illustrate the technique of going backwards through an array. As I goes from 1 to 10, K goes from 10 to 1. The increment value in a DO statement must be positive, therefore,
DO 2 I=1,10  
K=11-I

provides a legal method of writing the illegal statement DO 2 K=10,1,-1.

DO 1 J=K,10  
1  L(J)=L(J)+L(J+1)

This inner DO loop generates the line of values output by statement number 2. When control reaches statement 2, the variable J can be used again because statement number 2 is outside the inner DO loop. However, if I were used in statement 2 instead of J, the statement 2 PRINT 3,(L(I),I=K,11) would be an error. Statement 2 is inside the inner DO loop and would change the value of the index from within the DO loop. Changing the value of a DO index from inside the loop is illegal and will cause a fatal error or a never ending loop.

PROGRAM PASCAL (OUTPUT)

K=11-I  
L(K)=1  
DO 1 J = K,10  
L(J)=L(J)+L(J+1)  
2 PRINT3,(L(J)*J=K,11)  
3 FORMAT(11I5)  
STOP  
END
**PROGRAM X**

Program X references a function EXTRAC which squares the number passed as an argument.

Features:

- Referencing a function
- Function type

Program X illustrates that a function type must agree with the type associated with the function name in the calling program.

**K=EXTRAC(K)**

Since the first letter of the function name EXTRAC is E, the function is implicitly typed real. EXTRAC is referenced, and the value 7 is passed to the function as an argument. However, the function subprogram is explicitly defined integer, INTEGER FUNCTION EXTRAC(K), and the conflicting types produce erroneous results.

The argument 7 is integer which agrees with the type of the dummy argument K in the subprogram. The result 49 is correctly computed. However, when this value is returned to the calling program, the integer value 49 is returned to the real name EXTRAC; and an integer value in a real variable produces an erroneous result (refer to program EQUIV).

This problem arises because the programmer and the compiler regard a program from different viewpoints. The programmer often considers his complete program to be one unit whereas the compiler treats each program unit separately. To the programmer, the statement

**INTEGER FUNCTION EXTRAC(K)**

defines the function EXTRAC integer. The compiler, however, compiles integer function EXTRAC and the main program separately. In the subprogram EXTRAC is defined integer, in the main program it is defined real. Information which the main program needs regarding a subprogram must be supplied in the main program - in this instance the type of the function.

There is no way for the compiler to determine if the type of a program unit agrees with the type of the name in the calling program; therefore, no diagnostic help can be given for errors of this kind.
PROGRAM X (OUTPUT)
C WITH EXTRAC DECLARED INTEGER THE RESULT SHOULD BE 49, OTHERWISE IT
C WILL BE ZERO
  K = EXTRAC(7)
PRINT 1, K
1 FORMAT (1H1, I5)
STOP
END

INTEGER FUNCTION EXTRAC(K)
EXTRAC = K*K
RETURN
END

Output:

0
PROGRAM VARDIM

Program VARDIM illustrates the use of variable dimensions to allow a subroutine to operate on arrays of differing size.

Features:

Passing an array to a subroutine as a parameter.

A subroutine name used as a parameter passes the address of the beginning of the array and no dimension information.

COMMON X(4,3)

Array X is dimensioned (4,3) and placed in common.

REAL Y(6)

Array Y dimensioned (6) is explicitly typed real. It is not in common.

CALL IOTA(X,12)

The subroutine IOTA is called. The first parameter to IOTA is array X, and the second parameter is the number of elements in that array, 12. The number of elements in the array rather than the dimensions (4,3) is used which is legal.

SUBROUTINE IOTA(A,M)
DIMENSION A(M)

Subroutine IOTA has variable dimensions. Array A is given the dimension M. Whenever the main program calls IOTA, it can provide the name and the dimensions of the array; since A and M are dummy arguments, IOTA can be called repeatedly with different dimensions replacing M at each call.

CALL IOTA(X,12)

When IOTA is called by the main program, the actual argument X replaces A; and 12 replaces M.
DO 1 I=1,M
  A(I)=I

The DO loop places the numbers 1 through 12 in consecutive elements of array X.

CALL IOTA(Y,6)

When IOTA is called again, Y replaces A and 6 replaces M; and numbers 1 through 6 are placed in consecutive elements of array Y. Notice the type of the arguments in the calling program agree with the type of the arguments in the subroutine. X and A are real, 12 and M are integer.

Names used in the subroutine are related to those in the calling program only by their position as arguments. If a variable I was in the calling program, it would be completely independent of the variable I in the subroutine IOTA.

The WRITE statement outputs the arrays X and Y.

```
PROGRAM VARDIM (OUTPUT, TAPE6=OUTPUT)
COMMON X(4,3)
REAL Y(6)
CALL IOTA(X,12)
CALL IOTA(Y,6)
WRITE (6,100) X,Y
100 FORMAT (*1ARRAY X = $12F6.0$5X,*ARRAY Y = $6F6.0$)
STOP
END
```

```
SUBROUTINE IOTA (A,M)
  C IOTA STORES CONSECUTIVE INTEGERS IN EVERY ELEMENT OF THE ARRAY A
  C STARTING AT 1
  DIMENSION A(M)
  DO 1 I = 1,M
  A(I)=I
  RETURN
END
```

```
ARRAY X = 1. 2. 3. 4. 5. 6. 7. 8. 9. 10. 11. 12. ARRAY Y = 1. 2. 3. 4. 5. 6.
```

60305600 A
PROGRAM VARDIM2

VARDIM2 is an extension of program VARDIM. Subroutine IOTA is used; in addition, another subroutine and two functions are used.

Features:

- Multiple entry points
- Variable dimensions
- EXTERNAL statement
- COMMON used for communication between program units
- Passing values through COMMON
- Use of library functions ABS and FLOAT
- Calling functions through several levels
- Passing a subprogram name as an argument

Program VARDIM2 describes the method of a main program calling subprograms and subprograms calling each other. Since the program is necessarily complex, each subprogram is described separately followed by a description of the main program.

SUBROUTINE IOTA

SUBROUTINE IOTA is described in program VARDIM.

SUBROUTINE SET

SUBROUTINE SET(A,M,V) places the value V into every element of the array A. The dimension of A is specified by M.

Subroutine SET has an alternate entry point INC. When SET is entered at ENTRY INC, the value V is added to each element of the array A. The dimension of A is specified by M.

The DO loop in subroutine SET clears the array to zero.
FUNCTION AVG

This function computes the average of the first J elements of common. J is a value passed by the main program through the function PVAL.

This function subprogram is an example of a main program and a subprogram sharing values in common. The main program declares common to be 12 words and FUNCTION AVG declares common to be 100 words. Function AVG and the main program share the first 12 words in common. Values placed in common by the main program are available to the function subprogram.

The number of values to be averaged is passed to FUNCTION PVAL by the statement 

\[ AA = PVAL(12, AVG) \]

and function PVAL passes this number to function AVG: 

\[ PVAL = ABS(WAY(SIZE)) \]

COMMON A(100)

Function AVG declares common 100 so that varying lengths (less than 100) can be used in calls. In this instance, only 12 of the 100 words are used.

\[
\begin{align*}
  & \text{DO 1 I=1,J} \\
  & 1 \quad \text{AVG=AVG+A(I)}
\end{align*}
\]

The DO loop adds the 12 elements in common.

\[ AVG=AVG/FLOAT(J) \]

This statement finds the average. The library function FLOAT is used to convert the integer 12 to a floating point (real) number to avoid mixed mode arithmetic.

The average is returned to the statement 

\[ PVAL = ABS(WAY(SIZE)) \]

in function PVAL.
FUNCTION PVAL

Function PVAL references a function specified by the calling program to return a value to the calling program. This value is forced to be positive by the library function ABS.

The main program first calls PVAL with the statement \( AA = PVAL(12, AVG) \), passing the integer value 12 and the function AVG as parameters.

INTEGER SIZE

PVAL declares SIZE integer - the type of the argument in the main program (integer 12) agrees with the corresponding dummy argument (SIZE) in the subprogram.

\( PVAL = \text{ABS}(\text{WAY}(\text{SIZE})) \)

The value of PVAL is computed. This value will be returned to the main program through the function name PVAL. Two functions are referenced by this statement; the library function ABS and the user written function AVG. The actual arguments 12 and AVG replace SIZE and WAY.

\( PVAL = \text{ABS}(\text{AVG}(12)) \)

Function AVG is called, and J is given the value 12. The average of the first 12 elements of common are computed by AVG and returned to function PVAL. Library function ABS finds the absolute value of the value returned by AVG.

\( AM = PVAL(12, \text{MULT}) \)

In this statement in the main program, PVAL is referenced again. This time the function MULT replaces WAY.

FUNCTION MULT

MULT multiplies the first and twelfth words in COMMON and subtracts the product from the average (computed by the function AVG) of the first \( J/2 \) words in common.

COMMON ARRAY(12)

Common is declared 12; MULT shares the first 12 words of common with the main program.
MULT=ARRAY(12)*ARRAY(1)-AVG(J/2)

The twelfth and first element in common are multiplied and the average of J/2 is subtracted. This is an example of a subprogram calling another subprogram - the function AVG is used to compute the average.

MAIN PROGRAM — VARDIM2

The main program calls the subroutines and functions described.

COMMON X(4,3)

Twelve elements in the array X are declared to be in common.

REAL Y(6)

The real array Y is dimensioned 6.

EXTERNAL MULT, AVG

Function names MULT and AVG are declared EXTERNAL. Before a subprogram name is used as an argument to another subprogram, it must be declared in an EXTERNAL statement in the calling program. Otherwise it would be treated by the compiler as a variable name.

CALL SET(Y,6,0.)

Subroutine SET is called. The arguments (Y,6,0.) replace the dummy arguments (A,M,V).

```
  DIMENSION Y (6)
  DO 1 I = 1,6
    1 Y(I) = 0.0
```

The array Y is set to zero. The NAMELIST output shows the 6 elements of Y contain zero.
CALL IOTA(X,12)

Subroutine IOTA is called. X and 12 replace the dummy arguments A and M

    DIMENSION X (12)
    DO 1 I=1,12
    1    X(I) = I

the value of the subscript is placed in each element of the array X. Program VARDIM output shows the value of X is 1 through 12.

CALL INC(X,12,-5.)

Subroutine SET is called, this time through entry point INC. The arguments (X,12,-5.) replace the dummy arguments (A,M,V)

    DO 2 I=1,12
    2    X(I) = X(I) + -5.

-5. is added to each element in the array X. Program VARDIM2 output shows X is now -4,-3,-2,-1,0,1,2,3,4,5,6,7

AA=PVAL(12,AVG)

Function PVAL is called and its value replaces AA.

AM=PVAL(12,MULT)

Function PVAL is called again with different arguments and the value replaces AM.

PROGRAM VARDIM2(OUTPUT,TAPE6=OUTPUT,DEBUG=OUTPUT)
C
   THIS PROGRAM USES VARIABLE DIMENSIONS AND MANY SUBPROGRAM CONCEPTS
COMMON X(4,3)
REAL Y(6)
EXTERNAL MULT, AVG
NAMELIST/V/X,Y,AA,AM
CALL SET(Y,6,0.)
CALL IOTA(X,12)
CALL INC(X,12,-5.)
AA=PVAL(12,AVG)
AM=PVAL(12,MULT)
WRITE(6,V)
STOP
END
SUBROUTINE SET (A,M,V)
C
SET PUTS THE VALUE V INTO EVERY ELEMENT OF THE ARRAY A
DIMENSION A(M)
DO1I=1,M
1 A(I)=0.0
C
ENTRY INC
C
INC ADDS THE VALUE V TO EVERY ELEMENT IN THE ARRAY A
DO 2 I = 1,M
2 A(I) = A(I) + V
RETURN
END

SUBROUTINE IOTA (A,M)
C
IOTA PUTS CONSECUTIVE INTEGERS STARTING AT 1 IN EVERY ELEMENT OF
C
THE ARRAY A
DIMENSION A(M)
DO1I=1,M
1 A(I)=I
RETURN
END

FUNCTION PVAL(SIZE,WAY)
C
PVAL COMPUTES THE POSITIVE VALUE OF WHATEVER REAL VALUE IS RETURNED
C
BY A FUNCTION SPECIFIED WHEN PVAL WAS CALLED. SIZE IS AN INTEGER
C
VALUE PASSED ON TO THE FUNCTION.
INTEGER SIZE
PVAL=ABS(WAY(SIZE))
RETURN
END

FUNCTION AVG(J)
C
AVG COMPUTES THE AVERAGE OF THE FIRST J ELEMENTS OF COMMON.
COMMON A(100)
AVG=0.
DO 1 I = 1,J
1 AVG=AVG+A(I)
AVG=AVG/FLOAT(J)
RETURN
END
REAL FUNCTION MULT(J)
C MULT MULTIPLIES THE FIRST AND TWELTH ELEMENTS OF COMMON AND
C SUBTRACTS FROM THIS THE AVERAGE (COMPUTED
C BY THE FUNCTION AVG) OF THE FIRST J/2 WORDS IN COMMON.
C
COMMON ARRAY(12)
MULT=ARRAY(12)*ARRAY(1)-AVG(J/2)
RETURN
END
PROGRAM CIRCLE

Program CIRCLE finds the area of a circle which circumscribes a rectangle.

Features:

Definition and use of both FUNCTION subprograms and statement functions.

This program has a hidden bug. We suggest you read the text from the start if you intend to find it.

A programmer wrote the following program to find the area of a circle which circumscribes a rectangle, and wrote a function named DIM to compute the diameter of the circle.

![Diagram of a circle circumscribing a square]

The area of a circle is $\pi R^2$, which is approximately the same as $3.1416/4 \times $Diameter$^2$.

```
PROGRAM CIRCLE (OUTPUT)
A=4.0
B=3.0
AREA=3.1416/4.0*DIM(A*B)**2
PRINT 1, AREA
1 FORMAT(G20.10)
STOP
END
FUNCTION DIM(X,Y)
DIM=SQR(T(X*X+Y*Y))
RETURN
END
```

Output:

```
.7854000000
```

60305600 A  II-1-35
The programmer was completely baffled by the result; he felt the area of a circle circumscribing a rectangle 12 square inches should be more than .785! He consulted another programmer who quickly pointed out that a simple function like DIM should have been written as a statement function. Since FORTRAN Extended compiles statement functions inline, it would execute much faster because no jump nor return jump would be generated by the function.

The programmer rewrote his program as follows:

```
PROGRAM CIRCLE (OUTPUT)
DIM(x+y)=SQR(x*x+y*y)
A=4.0
B=3.0
AREA=3.1416/4.0*DIM(A*B)**2
PRINT 1, AREA
1 FORMAT (G20.10)
STOP
END
```

and obtained the correct result.

When the programmer wrote his function subprogram, he used the same name as a library intrinsic function. If the name of an intrinsic function is used for a user written function, the user written function is ignored.
Since the character set is selected when FORTRAN Extended is installed, the user should check with his installation to determine which character set is being used.

Installation options allow the user to select an 026 or an 029 keypunch, or to override this selection by punching a 26 or 29 in columns 79 and 80 of the SCOPE job card, or any 7/8/9 end-of-record card. The keypunched 26 or 29 remains in effect for the remainder of the job or until it is reset by a different mode selection on another 7/8/9 card.

†When the 63-Character Set is used, the punch code 8-2 is associated with display code 63, the colon. Display code 00g is not included in the 63-Character Set and is not associated with any card punch. The 8-6 card punch (026 keypunch) and the 0-8-4 card punch (029 keypunch) in the 63-Character Set are treated as blank on input.

*Since 00 cannot be represented on magnetic tape, it is converted to BCD 12. On input, it will be translated to display code 33 (number zero).
Diagnostic messages are produced by the FORTRAN Extended compiler during both compilation and execution to inform the user of errors in the source program, input data or intermediate results.

**COMPIATION DIAGNOSTICS**

Errors detected during compilation are noted on the source listing immediately following the END card. The format of the message is as follows:

<table>
<thead>
<tr>
<th>CARD NO.</th>
<th>SEVERITY</th>
<th>DIAGNOSTIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>e</td>
<td>a error message</td>
</tr>
</tbody>
</table>

n  Card number where error was detected. This number is assigned by the FORTRAN Extended compiler.

e  Indicates the type of diagnostic: I, FC, FE, ANSI

I  Informative message which indicates minor syntax errors or omissions which have no effect upon compilation or execution.

FC  When an error of this type is encountered during compilation, the remaining portion of the program is checked for syntax errors only. Program is not executed.

FE  Error fatal to execution. Program compiles but does not execute.

ANSI  Usage does not conform to ANSI standards (X3.0 - 1966). ANSI diagnostics are not listed unless the X parameter is specified on the FTN control card.

a  Information in this column will differ according to the type of error encountered. For example, if the same statement label is used more than once, the label number is printed. If a message of the format cn CD n appears, cn is the column number in which the error was detected, and n is the card number.

error message  Error message printed by FORTRAN Extended compiler

THE ECS STATEMENT IS OBSOLETE. USE A LEVEL 3 STATEMENT.

ARG TO LOCF MAY NOT BE AN EXPRESSION
EXECUTION DIAGNOSTICS

Execution errors are fatal unless a non-standard recovery routine is specified by the user (refer to section 3, part 3).

Execution diagnostics are printed on the source listing in the following format:

```plaintext
ERROR NUMBER x DETECTED BY routine AT ADDRESS y

CALLED FROM routine AT ADDRESS z

or CALLED FROM routine AT LINE d

ERROR SUMMARY

ERROR TIMES

x    n
```

y and z are addresses, x is a decimal error number, and d is a line number as printed on the source listing. n is a decimal digit which indicates the number of times the error occurred.

Example:

```plaintext
PROGRAM EXERR(INPUT,OUTPUT)
  N=5
  GO TO (1,2,3), N
  1 N=N+1
  2 N=N+2
  3 STOP
END
```

```plaintext
ERROR IN COMPUTED GOTO STATEMENT- INDEX VALUE INVALID
ERROR NUMBER   0001 DETECTED BY ACGOER AT ADDRESS 000001
CALLED FROM EXERR AT LINE 0003
```

In the following list of execution diagnostics:

- R = an argument
- I and J = integer
- Y and X = real
- D = double precision
- Z = complex

The SYSTEM routine handles error tracing, diagnostic printing, termination of output buffers, and transfer to specified non-standard error procedures. All FORTRAN mathematical routines rely on SYSTEM to complete these tasks; also, a FORTRAN coded routine may call SYSTEM. Any argument used by SYSTEM relating to a specific error may be changed by a user routine during execution. The END processor also makes use of SYSTEM to dump the output buffers and print an error summary. Since the following routines must always be available, they are combined into one subprogram with multiple entry points.

Q8NTRY. Initializes input/output buffer parameters

STOP. Enters STOP in dayfile and begins END processing

EXIT. Enters EXIT in dayfile and begins END processing

END. Terminates all output buffers, prints an error summary, transfers control to the main overlay if within an overlay; in any other case exits to monitor.

SYSTEM Handles error tracing, diagnostic printing, termination of output buffers; and depending on type of error, transfers to specified non-standard error recovery address, terminates the job, or returns to calling routine.

SYSTEMC Changes entry to SYSTEM's error table according to arguments passed.

CALLING SYSTEM

The calling sequence to SYSTEM passes the error number as the first argument and an error message as the second argument; therefore, several messages may be associated with one error number. The error summary at program termination lists the total number of times each error number was encountered.
ERROR PROCESSING

The error number of zero is accepted as a special call to end the output buffers and return. If no OUTPUT file is defined before SYSTEM is called, no errors are printed and a message to this effect appears in the dayfile. Each line printed is subjected to the line limit of the OUTPUT buffer; when the limit is exceeded, the job is terminated.

The error table is ordered serially (the first error corresponds to error number 1) and it is expandable at assembly time. The last entry in the table is a catch-all for any error number that exceeds the table length. An entry in the error table appears as follows:

<table>
<thead>
<tr>
<th>Print Frequency</th>
<th>Frequency Increment</th>
<th>Print Limit</th>
<th>Detection Total</th>
<th>F/NF</th>
<th>A/NA</th>
<th>Non-standard Recovery Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>8</td>
<td>12</td>
<td>12</td>
<td>1</td>
<td>1</td>
<td>18</td>
</tr>
</tbody>
</table>

Print frequency is used as follows:

<table>
<thead>
<tr>
<th>Print Frequency</th>
<th>Increment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Diagnostic and traceback information are not listed.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Diagnostic and traceback information are listed until the print limit is reached.</td>
</tr>
<tr>
<td>0</td>
<td>n</td>
<td>Diagnostic and traceback information are listed only the first n times unless the print limit is reached first.</td>
</tr>
<tr>
<td>n</td>
<td></td>
<td>Diagnostic and traceback information are listed every nth time until the print limit is reached.</td>
</tr>
</tbody>
</table>
STANDARD RECOVERY

If the error is non-fatal (NF), and no non-standard recovery address is specified; error messages are printed according to print frequency, and control is returned to the calling routine.

If the error is fatal (F), and no non-standard recovery address is specified, error messages are printed according to print frequency, an error summary is listed, all output buffers are terminated, and the job is terminated.

NON-STANDARD RECOVERY

If a non-standard recovery is specified, SYSTEM supplies the recovery routine with the following information:

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A1</td>
<td>Address of argument list passed to routine detecting the error</td>
</tr>
<tr>
<td>X1</td>
<td>Address of first argument in the list</td>
</tr>
<tr>
<td>A0</td>
<td>Address of argument list of routine that called the routine detecting the error</td>
</tr>
<tr>
<td>B1</td>
<td>Address of a secondary argument list which contains, in successive words:</td>
</tr>
<tr>
<td></td>
<td>Error number passed to SYSTEM</td>
</tr>
<tr>
<td></td>
<td>Address of diagnostic word available to SYSTEM</td>
</tr>
<tr>
<td></td>
<td>Address within auxiliary table if A/NA bit is set, otherwise zero</td>
</tr>
<tr>
<td></td>
<td>Instruction consisting of RJ to SYSTEM in upper 30 bits and traceback information in lower 30 bits for routine that called SYSTEM</td>
</tr>
<tr>
<td>A2</td>
<td>Address of error table entry in SYSTEM</td>
</tr>
<tr>
<td>X2</td>
<td>Contents of error table entry</td>
</tr>
</tbody>
</table>

Information in the secondary argument list is not available to FORTRAN-coded routines.
NON-FATAL ERROR

The routine detecting the error and SYSTEM are delinked from the calling chain, and the non-standard recovery routine is entered. When the recovery routine exits in the normal manner, control returns to the routine that called the routine detecting the error.

Thus, any faulty arguments can be corrected, and the recovery routine is allowed to call the routine which detected the error, providing corrected arguments. By not correcting the faulty arguments in the recovery routine, a three routine loop can develop between the routine which detects the error, SYSTEM, and the recovery routine. No checking is done for this case.

FATAL ERROR

SYSTEM calls the non-standard recovery routine in the normal fashion, with the registers set as indicated above. If the non-standard recovery routine exits in the normal fashion and returns control to SYSTEM, the recovery routine is free to continue computation.

A/NA BIT

The A/NA bit is used only when a non-standard recovery address is specified.

If this bit is set, the address within an auxiliary table is passed in the third word of the secondary argument list to the recovery routine. This bit allows more information than is normally supplied by SYSTEM to be passed to the recovery routine. The bit may be set only during assembly of SYSTEM, as an entry must also be made into the auxiliary table. Each word in the auxiliary table must have the error number in its upper 10 bits, so that the address of the first error number match is passed to the recovery routine. An entry in the auxiliary table for an error is not limited to any specific number of words.
The traceback information is terminated as soon as one of the following conditions is detected:

The calling routine is a program.

The maximum traceback limit is reached.

No traceback information is supplied.

To change an error table during execution, a FORTRAN call is made to SYSTEMC with the following arguments:

Error number

List containing consecutive locations:

<table>
<thead>
<tr>
<th>Word</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Fatal/non-fatal (fatal = 1, non-fatal = 0)</td>
</tr>
<tr>
<td>2</td>
<td>Print frequency</td>
</tr>
<tr>
<td>3</td>
<td>Print frequency increment (only significant if word 2 = 0)</td>
</tr>
<tr>
<td></td>
<td>special values:</td>
</tr>
<tr>
<td></td>
<td>word 3 = 0 never list error</td>
</tr>
<tr>
<td></td>
<td>word 3 = 1 always list error</td>
</tr>
<tr>
<td></td>
<td>word 3 = x list error only the first x times</td>
</tr>
<tr>
<td>4</td>
<td>Print limit</td>
</tr>
<tr>
<td>5</td>
<td>Non-standard recovery address</td>
</tr>
<tr>
<td>6</td>
<td>Maximum traceback limit</td>
</tr>
</tbody>
</table>

If any word in the argument list is negative, the value already in table entry is not to be altered.

(Since the auxiliary table bit can be set only during assembly of SYSTEM, only then can an auxiliary table entry be made.)
FILE NAME HANDLING BY SYSTEM

The file names in the PROGRAM statement are placed in RA+2 and the locations immediately following by SYSTEM (Q8NTRY). RA is the reference address, the absolute address where the user's field length begins. The file name is left justified, and the file's file information table (FIT) address is right justified in the word.

The logical file name (LFN) which appears in the first word of the file information table is determined in one of three ways:

1. If no arguments are specified on the load card, the logical file name is the file name in the PROGRAM statement.

   Example:

   ```
   F8N.
   LG0.
   .
   .
   PROGRAM TEST1(INPUT,OUTPUT,TAPE1,TAPE2)
   ```

   Contents of RA+2 before execution of Q8NTRY:

   000 ... 000
   000 ... 000

   Contents of RA+2 after execution of Q8NTRY:  The logical file names in the file information table will be:

   INPUT ... fit address
   OUTPUT ... fit address
   TAPE1 ... fit address
   TAPE2 ... fit address

   INPUT
   OUTPUT
   TAPE1
   TAPE2

2. If file names are specified on the load card, the logical file name is the name specified on the load card. If no file names are specified on the load card, it is the file name from the PROGRAM statement. A one-to-one correspondence exists between parameters on the load card and parameters in the PROGRAM statement.

   Example:

   ```
   F8N.
   LG0(,,DATA,ANSW)
   .
   .
   PROGRAM TEST2(INPUT,OUTPUT,TAPE1,TAPE2,TAPE3-TAPE1)
   ```
Contents of RA+2 before execution of Q8NTRY:

000 ... 000
000 ... 000
DATA .. 000
ANSW .. 000

Contents of RA+2 after execution of Q8NTRY:

INPUT ... fit address
OUTPUT .. fit address
TAPE1 ... fit address
TAPE2 ... fit address
TAPE3 ... fit address of TAPE1

The logical file names in the file information table will be:

INPUT
OUTPUT
DATA
ANSW

3. If a file name in the PROGRAM statement is equivalence, the logical file name is the file to the right of the equal sign. No new file information table is created.

Example:

**FTN.**

L60(DATA,ANSW)
.
.
.
PROGRAM TEST3(INPUT,OUTPUT,TAPE1=OUTPUT,TAPE2,TAPE3)

Contents of RA+2 before execution of Q8NTRY:

000 ... 000
000 ... 000
DATA .. 000
ANSW .. 000

Contents of RA+2 after execution of Q8NTRY:

INPUT ... fit address
OUTPUT .. fit address
TAPE1 ... fit address of OUTPUT
TAPE2 ... fit address
TAPE3 ... fit address

The logical file names in the file information table will be:

INPUT
OUTPUT
uses OUTPUT file information table
ANSW
TAPE3
FLOATING POINT ARITHMETIC

Floating point arithmetic is carried out in the functional units of the central processor.

In the 60-bit floating point format shown above, the binary point is considered to be to the right of the coefficient. The lower 48 bits express the integer coefficient, which is the equivalent of approximately 14 decimal digits. The sign of the number is the highest order bit of the packed word. Negative numbers are represented by the one's complement of the 60-bit number.

The exponent portion of the floating point format is biased by 2000 octal. This particular format for floating point numbers was chosen so that the packed form may be treated as a 60-bit integer for sign, equality and zero tests. (Refer to 6400/6500/6600 Computer Systems Reference Manual or 7600 Computer System Reference Manual for details of the hardware pack instruction.)

The following table summarizes the configurations of bits 58 and 59 and the signs of the possible combinations. The number is negative if bit 59 is 1 and positive if bit 59 is 0.

<table>
<thead>
<tr>
<th>Bit 59</th>
<th>Coefficient Sign</th>
<th>Bit 58</th>
<th>Exponent Sign</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Positive</td>
<td>1</td>
<td>Positive</td>
</tr>
<tr>
<td>0</td>
<td>Positive</td>
<td>0</td>
<td>Negative</td>
</tr>
<tr>
<td>1</td>
<td>Negative</td>
<td>0</td>
<td>Positive</td>
</tr>
<tr>
<td>1</td>
<td>Negative</td>
<td>1</td>
<td>Negative</td>
</tr>
</tbody>
</table>
To add or subtract two floating point numbers, the floating point ADD unit enters the coefficient with the smaller exponent into the upper half of an accumulator and shifts it right by the difference of the exponents. Then it adds the other coefficient into the upper half of the accumulator. The result is a double length register with the following format:

![Diagram showing the structure of a floating point number with 95 most significant bits, 47 least significant bits, and a binary point between them.]

If single precision is selected, the result is the upper 48 bits of the 96-bit result and the larger exponent. Selecting double precision causes the lower 48 bits of the 96-bit result and the larger exponent minus 60 octal (or 48) to be returned as the result. The subtraction of 60 octal (or 48) is necessary because effectively, the binary point is moved from the right of bit 48 to the right of bit 0.

The multiply units generate 96-bit products from two 48-bit coefficients. The result of a multiply operation is a double length register with the following format:

![Diagram showing the structure of a floating point number with 95 most significant bits, 47 least significant bits, and a binary point between them.]

When unrounded instructions are used, the upper and lower half results with proper exponents may be recovered separately; when rounded instructions are used, only upper half results may be obtained.

If single precision is selected, the upper 48 bits of the product and the sum of the exponents plus 60 octal (or 48) are returned as the result. The addition of 60 octal (or 48) is necessary because, effectively, the binary point is moved from the right of bit 0 to the right of bit 48 when the upper half of the 96-bit result is selected. If double precision is selected, the lower 48 bits of the product and the sum of the exponents is the result.

Some examples of floating point numbers are shown below in octal notation.

- Normalized floating point +1 = 1720 4000 0000 0000 0000
- Normalized floating point +100 = 1726 6200 0000 0000 0000
- Normalized floating point -100 = 6051 1577 7777 7777 7777
- Normalized floating point 10^{+64} = 2245 6047 4037 2237 7733
- Normalized floating point 10^{+65} = 6404 2570 0025 6605 5317

III-4-2

60305600 A
OVERFLOW ($+\infty$ or $-\infty$)

Overflow of the floating point range is indicated by an exponent of 3777 for a positive result and 4000 for a negative result. These are the largest exponent values that can be represented in floating point format, as shown in the floating point table. If the computed value of an exponent is exactly 3777 or 4000, a partial overflow condition exists. The error mode 2 flag is not set by a partial overflow. However, any further computation in floating point functional units with this exponent will set an error mode 2 flag. A complete overflow occurs when a floating point functional unit computes a result that requires an exponent larger than 3777 or 4000.

In this case the result is given a 3777 or 4000 exponent and a zero coefficient. The sign of the coefficient remains the same, as if the result had not exceeded the floating point range. Any further computation in floating point functional units with this result sets an error mode 2 flag.

In this case, the result is given a 3777 or 4000 exponent and a zero co-efficient. The sign of the coefficient remains the same, as if the result had not exceeded the floating point range. The coefficient calculation is ignored, and the overflow condition flag is set in the Program Status Designator (PSD) register. When the overflow condition occurs, the overflow flag in the PSD register causes an error mode 2 message to be printed. Printing an error mode 2 message is the default condition; alternative actions can be specified by the user (refer to SCOPE Reference Manual).

UNDERFLOW ($+0$ or $-0$)

Underflow of the floating point range is indicated by an exponent of 0000 for positive numbers and 7777 for negative numbers, the smallest exponent values that can be represented in floating point format. If these exponent values happen to be the exact representation of a result, a partial underflow condition exists; and the underflow condition flag is not set. However, further computation in floating point functional units with these exponents may set the underflow condition flag.

A complete underflow occurs when a floating point functional unit computes a result that requires an exponent smaller than 0000 or 7777. In this case the result is given a 0000 or 7777 exponent and zero coefficient. The sign of the coefficient will be the same as that generated if the result had not fallen short of the floating point range. Thus, the complete underflow indicator is a word of all zero bits, or all one bits, depending on the sign. It is the same as a zero word in integer format.

No underflow indicator is set and no error message is printed.

A complete underflow occurs for this instruction whenever the exponent computation results in less than -1776 octal. This situation is sensed as a special case, and a complete zero word with proper sign results; the coefficient calculation is ignored, and the underflow condition flag is set in the PSD register. When the underflow condition occurs, the underflow flag in the PSD register causes an error mode 2 message to be printed. Printing an error mode 2 message is the default condition; alternative actions can be specified by the user (refer to SCOPE Reference Manual).
INDEFINITE RESULT

An indefinite result indicator is generated by a floating point functional unit when a calculation cannot be resolved; such as a division operation where the divisor and the dividend are both zero. Another case is multiplication of an overflow number times zero. An indefinite result is a value which cannot occur in normal floating point calculations. An indefinite result is represented by a minus zero exponent and a zero coefficient (17770 -0).

Any floating point functional unit receiving an indefinite indicator as an operand will generate an indefinite result regardless of the other operand value, and set an error mode 4 flag.

---

</table>

* In absolute value.

** An indefinite operand with a negative sign can occur only from packing or Boolean operations.
NON-STANDARD FLOATING POINT ARITHMETIC

Indefinite result indications:

0000X-----X = positive zero (+0)
7777X-----X = negative zero (-0)
3777X-----X = positive infinity (+∞)
4000X-----X = negative infinity (-∞)
1777X-----X = positive indefinite (+IND)
6000X-----X = negative indefinite (-IND)

where X is an unspecified octal digit.

If the correct result of an operation coincides with any of the above exponents, no error flag is set.

When a floating point arithmetic unit uses one of these six special forms as an operand, however, only the following octal words can occur as results and the associated error mode flag is set.

37770------0 = positive infinity (+∞)  Overflow condition flag
40007------7 = negative infinity (-∞)  Overflow condition flag
17770------0 = positive indefinite (+IND)  Indefinite condition flag
00000------0 = positive zero (+0)  Underflow condition flag

The following tabulations show results of the add, subtract, multiply and divide operations using various combinations of infinite, indefinite, and zero quantities as operands. The designations w and n are defined as follows:

w = any word except ±∞, IND
n = any word except ±∞, IND, or ±0

**INTEGER ARITHMETIC**

Central processor has no 60-bit integer multiply or divide instructions. Integer multiplication and division are performed with 48-bit arguments. The exponent of the result is set to zero. 48-bit integer multiplication is performed with an integer multiply instruction, but integer division must be performed in the floating divide unit. Integer arithmetic is accomplished by putting the integers into unnormalized floating point format using the pack instruction with a zero exponent value.

In integer division, the exponent of the resulting quotient is removed and the result is shifted to compensate for the fact that the result was normalized. In FORTRAN Extended, integer results of multiplication or division are expressed within 48 bits. Full 60-bit one's complement integer sums and differences are possible internally as the central processor has integer addition and subtraction instructions. However, because the binary-to-decimal conversion routines use multiplication and division, the range of integer values output is limited to those which can be expressed with 48 bits.

**DOUBLE PRECISION**

Although complete arithmetic instructions using double precision arguments are not provided by the hardware, the FORTRAN compiler generates code for true double precision by using instructions which give upper and lower half results with single precision arguments.
COMPLEX

Complex arithmetic instructions are not provided by hardware. The FORTRAN compiler generates code for complex arithmetic by using single precision floating point instructions.

LOGICAL AND MASKING

Logical and masking operations are provided by hardware logical instructions which operate on the entire 60-bit word (refer to section 2, part 1).

ARITHMETIC ERRORS

Under the SCOPE operating system arithmetic errors are classified at execution time as mode 1 - 7:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Error</th>
</tr>
</thead>
</table>
| 1    | Address out of range  
      | Reference to LCM or SCM outside established limits  
      | LCM or SCM block range |
| 2    | Operand is an infinite number |
| 3    | Address out of range or operand is infinite number |
| 4    | Indefinite operand |
| 5    | Address out of range or indefinite operand |
| 6    |Operand is infinite or indefinite number |
| 7    |Operand is infinite, indefinite or address is out of range |
Mode 1  
Address out of range. A non-existent storage location has been referenced. Mode 1 errors may be caused by:

- calling a non-existent subprogram during execution
- using an incorrect number of arguments when calling a subprogram
- a subscript assuming an illegal value
- no dimensions specified for an array name

Mode 2  
Infinite operand. One of the operands in a real operation is infinite. Infinity is the result whenever the true result of a real operation would be too large for the computer, or when division by zero is attempted. A value of infinity may be returned when some functions are referenced. For example, ALOG(0.) would be negative infinity.

In the following example, Z would be given the value infinity, and when the addition Z + 56. is attempted execution terminates with a mode 2 error.

```
1 FORMAT (F12.3)
    Y = 0.
    Z = 23.2/Y
PRINT 1, Z
CAT = Z + 56.
```

When the print statement is executed, an R is printed to indicate an out of range value.

Mode 3  
Address is out of range or operand is infinite number.

Mode 4  
Indefinite operand. One of the operands in a real operation is indefinite. An indefinite result is produced by dividing 0. by 0. or multiplying an infinite operand by 0. An illegal library function reference may return an indefinite value. For example, SQRT (-2.) would produce an indefinite result. An attempt to print an indefinite value produces the letter I.

Mode 5  
Address is out of range or indefinite operand.

Mode 6  
Operand is infinite or indefinite. A mode 6 arithmetic error occurs when a real operation is performed with one operand infinite and the other operand indefinite.

Mode 7  
Operand is infinite, indefinite, or address is out of range.

When an arithmetic error occurs the following type of message appears in the dayfile and execution is terminated:

```
14.39.06.ERROR MODE = 2 ADDRESS =002135
```

When an arithmetic error occurs, the following type of message appears in the dayfile.

```
14.30.36*00012.059*SYS. SC006 SCM DIRECT RANGE
```
The arithmetic error messages are listed under the following headings:

**CODE, MESSAGE AND MEANING, and LEVEL.**

**CODE xxnnn**

xx     SC or JM
nnn

**MESSAGE AND MEANING**

The message and an interpretation (if necessary) are printed.

**LEVEL**

Indicates the level of severity of the error as follows:

| X   | Job terminates. No EXIT processing occurs. |
| F   | Job terminates. EXIT processing occurs.    |
| W   | Warning message is printed, and error is ignored. Processing continues, although the portion of the program containing the error may not be executed. |
| I   | Informative message is printed.            |

**CODE**  
**MESSAGE AND MEANING**  
**LEVEL**

| SC001 | LCM PARITY  | F    |
| SC002 | SCM PARITY  | F    |
| SC003 | LCM BLOCK RANGE | F |
| SC004 | SCM BLOCK RANGE | F |
| SC005 | LCM DIRECT RANGE | F |
| SC006 | SCM DIRECT RANGE | F |
| SC007 | PROGRAM RANGE | F |
| SC008 | BREAKPOINT | F |
| SC009 | STEP CONDITION | F |
| SC010 | INDEFINITE CONDITION | F |
TRACING ARITHMETIC ERRORS

The following example outlines a method for detecting the location of an arithmetic error. When the following program is executed:

```
PROGRAM ERR (OUTPUT,TAPE1=OUTPUT)
NAMELIST /OUT/T,E
DATA T,E/5.,1./
1 WRITE (1,OUT)
   E = E/T + 1.
   T = T - 1.
   GO TO 1
END
```

this message appears in the dayfile:

```
07.11.39.ERROR MODE = 2. ADDRESS =002146
```

2146 is one plus the address at which the error was detected. The error was detected at address 2145. To locate this address in the program, turn to the Load Map and read the entries under PROGRAM AND BLOCK ASSIGNMENTS.

<table>
<thead>
<tr>
<th>BLOCK</th>
<th>ADDRESS</th>

<td></td>
</tr>
<tr>
<td>/GET,BT/</td>
<td>4246</td>
<td>5</td>
<td>SYSDIO-L</td>
</tr>
<tr>
<td>BTRT, SQ</td>
<td>4253</td>
<td>130</td>
<td></td>
</tr>
</tbody>
</table>

The user program ERR occupies storage locations 100 through 2161, systems program NAMOUT= occupies locations 2162 through 2742, SYSTEMS 2743 through 3626, GETFIT$ 3627 through 3660, etc. Location 2145 lies between 100 and 2162 and is therefore in the main program ERR. It is location 2045 relative to the beginning of ERR (all locations are relative to the first word address of the program load) 2145 - 100 = 2045 (octal).
This message appears in the dayfile:

SYS. SColl - OVERFLOW CONDITION

The address at which the error occurred is given in the dump of the exchange package for the program.

To locate this address in the program turn to the Load Map and read the entries under BLOCK ADDRESS.

The source listing of ERR includes the following code:

```
PROGRAM ERR (OUTPUT,TAPE1=OUTPUT)
NAMELIST /OUT/T,E
DATA T,E/5.0,1./
1 WRITE (1,OUT)
   5 E = E/T + 1.
   T = T - 1.
   GO TO 1
END
```

Checking the reason for the error (Arithmetic Error Mode 2 which indicates a real arithmetic error), check the output of the program and the logic of the source program. It becomes apparent that T assumes the value 0, and division by 0. is attempted in statement E = E/T + 1. A mode 2 error which signifies an infinite operand can be caused by division by 0. Therefore, the error was caused by statement 06 where division by 0. was attempted.

† Must be blocked one record per block
Buffer statements only

FORTRAN DEFAULT CONVENTIONS (SEQUENTIAL FILES)

File organization = Sequential

Block type = I for unformatted, C for formatted
No blocking

Record type = W for unformatted, Z for formatted

External character code = Display code
Label type = Unlabeled

Maximum block length = 5120 characters

Positioning before first access = No rewind

Positioning of current volume before swap = Unload

Positioning after last access = No rewind

Processing direction = Input/output

Error options = A (accept)

Error options = T (terminate) for READ/WRITE, AD (accept and display) for BUFFER input/output

Suppress multiple buffer = No (Record Manager anticipates user requirements)

Conversion mode = No

A unit record is one W format record. One formatted WRITE can create several unit records. One formatted read can process as input several unit records.

The default values for files named INPUT, OUTPUT and PUNCH are:

Block type C and record type Z.

Buffer input/output files default to C type blocks and S type records.

The appropriate conversion mode is set for all buffer input/output operations.

The conversion mode is set prior to the first open and cannot be changed during the processing of a file.

**FORTRAN DEFAULT CONVENTIONS (RANDOM FILES)**

When a file is processed using mass storage subroutines, the following file attributes are provided by the FORTRAN compiler:

File organization = Word addressable

Record type = W

Positioning before first access = None       Rewind
Positioning after last access = Unchanged              Rewind

Processing direction = Input/output

Error options = AD (accept and display)

Suppress multiple buffer = YES (Record Manager does not anticipate file access)

Block type, external character code, label type, maximum block length, positioning of current volume before swap, character conversion and label creation/checking are not applicable.

One WRITMS creates one W format record. One READMS reads one W format record. The master index is the last W format record in the file. If the length specified for a READMS is longer than the record, the excess locations in the user area are not changed by the read. If the record is longer than the length specified for a READMS, the excess words in the record are skipped.

ADDITIONAL BLOCK AND RECORD TYPES

FILE Control Cards: The FORTRAN programmer can use the Record Manager FILE control card to override the default values supplied by the FORTRAN compiler. This control card is described in 6000 Record Manager Reference Manual. The 7600 programmer can use the FILE control card to access record types other than W. This control card is described in 7600 SCOPE Reference Manual. Section 6, part 3 describes the FORTRAN/Record Manager interface.

BLOCK TYPES

Any block type consistent with the record type can be specified in the FILE control card because the FORTRAN language does not contain any statements which specify or constrain the block type.

RECORD TYPE

Although FORTRAN does not contain statements which specify the record type, constraints are imposed on the processing of certain types of records because of the logical structure of the records. When specifying record types in the FILE control card, the FORTRAN programmer must be aware of the following constraints:
<table>
<thead>
<tr>
<th>Record Type</th>
<th>Action Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>User must insert the record length on write. The length field must have leading zeros, not blanks, and must be within the buffer length used by the FORTRAN object time input/output routines.</td>
</tr>
<tr>
<td>R</td>
<td>User must insert the record mark on write.</td>
</tr>
<tr>
<td>B</td>
<td>User must insert the record length on write.</td>
</tr>
<tr>
<td>T</td>
<td>User must insert the trailer count field; it must have leading zeros not blanks. The same buffer restrictions apply as for D format records.</td>
</tr>
<tr>
<td>F</td>
<td>User must ensure fixed length records. Records larger than the fixed length are truncated; shorter records are padded with blanks.</td>
</tr>
</tbody>
</table>
| Z           | User must ensure that the character configuration used as a line terminator (two colons) does not occur at the low order byte position of a 60-bit word.  
User must also ensure recording mode is set to unformatted for tape. |
| U           | User must ensure that only one record per block is written. Only block type K, one record per block, is allowed with U type records.  
BUFFER statements only. |
| S           | User must be aware that each record (as defined on page 5-1) may occupy several physical records.  
User must be aware that each record is an S record. |
This deck illustrates the use of the FILE card to override default values supplied by the FORTRAN compiler. The following values are used:

Label Type = standard labels (LT=ST)
Block Type = character count (BT=C)
Maximum Block Length = 1000 characters (MBL=1000)
Record Type = fixed length (RT=F)
Record Length = 100 characters (FL=100)
This deck illustrates the use of the FILE card to override default values supplied by the FORTRAN compiler. The following values are used:

Label Type = unlabeled
Block type = character count
Maximum block length = 1000 characters
Record type = fixed length
Record length = 100 characters
Conversion mode ' = YES
External code = BCD

Assuming the source program is using formatted writes and 100-character records are always written, the file will be written on magnetic tape in 1000-character blocks (except possibly the last block) with even parity, at 800 bpi. No labels will be recorded, and no information will be written other than that supplied by the user. Records will be blocked 10 to a block.
**BACKSPACE/REWIND**

Backspacing on FORTRAN files repositions them so that the last logical record becomes the next logical record.

**BACKSPACE** is permitted only for files with F, S, or W record format or tape files with one record per block.

The user should remember that formatted input/output operations can read/write more than one record; unformatted input/output and BUFFER IN/OUT read/write only one record.

The rewind operation positions a magnetic tape file such that the next FORTRAN input/output operation references the first record. A mass storage file is positioned to the beginning of information.

The following table details the actions performed prior to positioning.

**BACKSPACE/REWIND**

<table>
<thead>
<tr>
<th>Condition</th>
<th>Device Type</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last operation was WRITE or BUFFER OUT</td>

<td></td>
<td>If the file is staged, the REWIND request has no effect. The file is staged and rewound when it is first referenced.</td>
</tr>
<tr>
<td></td>
<td>Mass Storage</td>
<td>REWIND request causes the file to be rewound when first referenced.</td>
</tr>
<tr>
<td>Previous operation was REWIND</td>
<td></td>
<td>Current REWIND is ignored.</td>
</tr>
</tbody>
</table>
**ENDFILE**

The ENDFILE operation introduces a delimiter into an input/output file. The following table shows the effect of ENDFILE on various record types.

<table>
<thead>
<tr>
<th>Record Type</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>W</td>
<td>Write end-of-partition. Terminate current block for magnetic tape file.</td>
</tr>
<tr>
<td>S</td>
<td>Terminate current block for magnetic tape file. Write level 17 zero length block.</td>
</tr>
<tr>
<td>Z with C blocking</td>
<td>Terminate current block for magnetic tape file. Write level 17 zero length block.</td>
</tr>
<tr>
<td>D.B.R.T</td>
<td></td>
</tr>
<tr>
<td>F.U. or Z</td>
<td>Terminate current block for magnetic tape file. Write level 17 zero length block.</td>
</tr>
</tbody>
</table>

A WRITE/BUFFER OUT can follow an ENDFILE operation. If the file has records of the format W, S, or Z with C blocking or it is a mass storage file with any other block/record formats, no special action is performed. However, if the file is assigned to magnetic tape and has a record format other than W, S, or Z with C blocking a tape mark is written preceding the requested record.
Labeled Files

Only files recorded on magnetic tape can be labeled files.

To process labeled files through a FORTRAN program, the SCOPE LABEL statement (refer to SCOPE Reference Manual) must specify a value for the label creation/checking parameter: either R which specifies an existing label is to be checked, or W which creates labels if no labels exist. The processing direction for sequential files in FORTRAN must be input/output to permit both READ and WRITE by a FORTRAN program on the file; therefore, the user must specify whether a labeled magnetic tape is used for input, or output/input/output.

If a file is declared to be labeled on a REQUEST control card, SCOPE compares the label (HDR1 only) with the label expected by the user. If the information does not compare and the use of the file is input, the job continues after instructions are entered from the system console. For output, a default label is written, and the job continues.

An object time subroutine, LABEL, is provided for the FORTRAN programmer to set up label information for Record Manager. If label information is properly set up, and subroutine LABEL is referenced prior to any other reference to the file, when the file is opened, the label and the information are compared for an input tape; or the information is written on an output tape.

Form of the call:

```
7 CALL LABEL (u,fwa)
```

u Unit number

fwa Address of first word containing the label information which must be in the mode and format discussed in the SCOPE Reference Manual.

Alternatively, the LABEL utility can be used (refer to SCOPE Reference Manual).
BUFFER INPUT/OUTPUT

The maximum lengths for physical records on tape can be exceeded using the BUFFER input/output statements if the L parameter on the SCOPE REQUEST control card is specified.

BUFFER IN/OUT statements can be used to achieve some degree of overlap between the user program and input/output with an external device (mass storage or tape). However, the memory area specified in the BUFFER IN/OUT statement will not be used as the physical record buffer. These buffers are maintained within an operating system buffer area in LCM. The execution of a BUFFER IN/OUT statement, therefore, involves movement of a record between system buffers in LCM and the memory area specified in the BUFFER IN/OUT statement. Correspondence between individual BUFFER statements and physical records on a device depends upon the block specification. For example, K blocking with a record count of one ensures that each BUFFER IN/OUT corresponds to a block.

BUFFER IN

1. Only one record is read each time a BUFFER IN is performed. If the length specified by the BUFFER statement is longer than the record read, excess locations are not changed by the read. If the record read is longer than the length specified by the BUFFER statement, the excess words in the record are ignored. The number of central memory words transmitted to the program block can be obtained by referencing the function LENGTH (section 8, part 1).

2. After using a BUFFER IN/OUT statement on unit u, and prior to referencing unit u or the contents of storage locations a through b, the status of the BUFFER operation must be checked by a reference to the UNIT function (section 8, part 1). This status check ensures that the data has actually been transferred, and the buffer parameters for the file have been restored.

3. If an attempt is made to BUFFER IN past an end-of-file without testing for the condition by referencing the UNIT function, the program terminates with the diagnostic:

   END OF FILE ENCOUNTERED file name

4. If the last operation on the file was a write operation, no data is available to read. If a read is attempted, the program terminates with the diagnostic:

   WRITE FOLLOWED BY READ ON FILE

5. If the starting address for the block is greater than the terminal address, the program terminates with the diagnostic:

   BUFFER DESIGNATION BAD FWA.GT.LWA, file name

6. If an attempt is made to BUFFER IN from an undefined file (a file not declared on the PROGRAM card), the program terminates with the diagnostic:

   UNASSIGNED MEDIUM, file name
BUFFER OUT

1. One record is written each time a BUFFER OUT is performed. The length of the record is the terminal address of the record (LWA) – starting address (FWA) + 1.

2. As with BUFFER IN, a BUFFER OUT operation must be followed by a reference to the UNIT function. This reference must occur prior to any other reference to the file.

3. If the terminal address is less than the first word address, the program terminates and the following diagnostic is issued:
   
   BUFFER SPECIFICATION BAD FWA.GT.LWA, file name

4. The UNASSIGNED MEDIUM diagnostic is similar to that issued from a BUFFER IN.

STATUS CHECKING

UNIT FUNCTION (BUFFERED INPUT/OUTPUT)

The UNIT function is used to check the status of a BUFFER IN or BUFFER OUT operation on logical unit u. The function returns the following values:

-1  Unit ready, no error  
+0  Unit ready, end-of-file encountered on the previous operation 
+1  Unit ready, parity error encountered on the previous operation

Example:

IF (UNIT(5)) 12,14,16

Control transfers to the statement labeled 12, 14 or 16 if the value returned was -1., 0., or +1. respectively.

If 0. or +1. is returned, the condition indicator is cleared before control is returned to the program. If the UNIT function references a logical unit referenced by input/output statements other than BUFFER IN/BUFFER OUT, the status returned will always indicate unit ready and no error (-1.).

Any of the following conditions encountered during a read result in end-of-file status:

   End of information
   Non-deleted W format flag record
   Embedded tape mark
   Terminating double tape mark
Terminating end of file label
Embedded zero length level 17 block
At end of section on INPUT file only

**EOF FUNCTION (NON-BUFFERED, INPUT/OUTPUT)**

The EOF function is used to test for an end-of-file read on unit u. Zero is returned if no end-of-file is encountered, or a non-zero value if end-of-file is encountered.

Example:

```
IF (EOF(5)) 10, 20
```

returns control to the statement labeled 10 if the previous read encountered an end-of-file, otherwise control goes to statement 20.

If an end-of-file is encountered, EOF clears the indicator before returning control.

If the previous operation on unit u was a write, EOF will return a zero value. An end-of-file condition exists only when an end-of-file is read.

This function has no meaning when applied to a random access file. If the EOF function is called in reference to such a file, a zero value would be returned.

Refer to the UNIT function for a list of conditions which result in an end-of-file status.

The user should test for an end-of-file after each READ statement to avoid input/output errors. If an attempt is made to read on unit u and an EOF was encountered on the previous read operation on this unit, execution terminates and an error message is printed.
Example:

If the values in storage are \(A = 10\), \(B = 44\), and \(C = 3\), and an EOF is reached after \(A\) is read, \(B\) and \(C\) are not read nor altered in memory.

```
READ 1, A, B, C
1 FORMAT (F4.2)
```

After the read statement, \(A\) will contain 24., \(B = 44\). and \(C = 3\). The end-of-file flag will be set. The job will be terminated if a subsequent READ is attempted without first executing an EOF check.

**IOCHEC FUNCTION**

The IOCHEC function tests for parity errors on non-buffered reads on unit \(u\). The value zero is returned if no error occurs.

Example:

```
J = IOCHEC(6)
IF (J) 15, 25
```

zero value would be returned to \(J\) if no parity error occurred and non-zero if an error had occurred; control would transfer to the statement labeled 25 or 15 respectively.

If a parity error occurred, IOCHEC would clear the parity indicator before returning. Parity errors are handled in this way regardless of the type of the external device.
PARITY ERROR DETECTION

A parity error status indicates that a parity error occurred within the current record. For non-buffered formatted files, the error did not necessarily occur within the last record requested by the program because the input/output routines read ahead one record whenever possible.

Parity errors are detected by the status checking functions on all read operations. When the write check option is specified on the REQUEST statement for the file (7600 SCOPE V2.0 Reference Manual) parity status may be checked on write operations which access mass storage files. Write parity errors for other types of devices (staged/on-line tape) are detected by the operating system, and a message is written in the dayfile.

When parity error status is returned, this does not necessarily refer to the immediately preceding operation because of the record blocking/deblocking performed by the Record Manager input/output routines via buffers in large core memory.

DATA INPUT ERROR CONTROL

The subprogram ERRSET allows a complete data set to be processed in one pass without premature termination due to errors; a listing is produced of all data errors and input diagnostics.

ERRSET (a,b) is called before a READ statement; it initializes an error count cell, a, and establishes a maximum number of errors, b. The program does not terminate when fatal errors are encountered until the limit, b, is reached. A maximum limit of $2^{32}-1$ can be specified.

The limit continues in effect for any subsequent READ statements until the number of errors specified has accumulated. The limit can be reset before a READ statement or turned off by setting b=0; b=0 is the equivalent of a normal read.

Example:

The following example illustrates the use of ERRSET to suppress normal fatal termination when large sets of data are being processed.
When ERRSET is called, a limit of 200 errors is established. The number of errors will be stored in KOUNT. After ARAY is read, KOUNT is checked. If errors occur, the following statements are not processed and a branch is made to statement 500. Had ERRSET not been called, fatal errors would have terminated the program before the branch to statement 500. At statement 500, ERRSET once more initializes the error count and compilation continues.

```
CALL ERRSET(KOUNT,200)
READ(1,125)(ARAY(I),I=1,1500)
125 FORMAT (3F10.5,E10.1)
   IF (KOUNT.GT.0) GO TO 500
   .
   .
500 CALL ERRSET(KOUNT,200)
   READ(1,125)(BRAY(I),I=1,1500)
   IF (KOUNT.GT.0) GO TO 600
   .
   .
600 CALL ERRSET(KOUNT,100)
   READ(1,230)(LRAY(I),I=1,500)
   PRINT 99, KOUNT
   READ(4,127)(MRAY(I),I=1,500)
   PRINT 99, KOUNT
   READ(4,225)(NRAY(I),I=1,50)
   .
   .
   .
   IF (KOUNT.GT.0) GO TO 700
   .
   .
700 CALL EXIT
END
```

Data errors and diagnostics are listed, providing the programmer with a list of errors for the entire program:
ERROR MESSAGES

ERROR IN COMPUTED GOTO STATEMENT- INDEX VALUE INVALID
ERROR NUMBER  0001 DETECTED BY ACGOER AT ADDRESS 000001
CALLED FROM EXERR AT LINE 0003

DIAGNOSTICS

1. Illegal Data in Field

   *ERROR DATA INPUT* ILLEGAL DATA IN FIELD
   **FORMAT NO. 125

2. Data overflow, exponent subfield has exceeded 323 (decimal) (data underflow, exponent less than -323.)

   *ERROR DATA INPUT* DATA OVERFLOW
   ** FORMAT NO. 125

3. Both illegal data and data overflow have been detected.

   *ERROR DATA INPUT* ILLEGAL DATA IN FIELD **
   AND DATA OVERFLOW ** FORMAT NO. 125

An error summary appears at the end of the program.

Error Summary:

PROGRAMMING NOTES

Meaningful results are not guaranteed in the following circumstances:

1. Mixed binary and display code files. For example, formatted and unformatted READ should not be mixed.

2. Mixed buffer input/output statements and read/write statements on the same file (without a REWIND in between).

3. Requesting a LENGTH function on a buffer unit before requesting a UNIT function.

4. Two consecutive buffer input/output statements on the same file without the intervening execution of a UNIT function call.
The FORTRAN user communicates with Record Manager through two types of FORTRAN CALL statements: calls that create, access, and modify the file information table and file commands that position and process files.

FILE INFORMATION TABLE CALLS

To place values in the file information table the user can call one of the following subroutines:

FILESQ for sequential files
FILEWA for word addressable files
FILEIS for indexed sequential files
FILEDA for direct access files

\[
\text{CALL FILExx (fit,keyword}_1\text{,value}_1\ldots \text{,keyword}_n\text{,value}_n)\]

xx \quad SQ, WA, IS, or DA

fit \quad Name of an array. Record Manager resides in the user’s field length, and the array must be large enough to contain both the file information table (FIT) and the file environment table (FET). 35 words should be allocated; 20 words for the file information table and 15 words for the file environment table. The file information table is created by the subroutine FILExx, beginning in the first word of the array. Record Manager supplies the information for the SCOPE file environment table, which is placed in the user’s array after the file information table.

keyword \quad Specifies a file information table field.

value \quad Value to be placed in the file information table field specified by the keyword.

All parameters, with the exception of fit, are paired; the first parameter is the keyword which indicates the field in the file information table, the second parameter is the value to be placed in the field. Only the pertinent parameters need be specified, and they may appear in any order. Since a FORTRAN call can contain a maximum of 63 parameters, 31 file information table fields can be specified with a FILExx call.
Example:

The following call sets up a file information table for a direct access file:

\[
\text{CALL FILEDA (FILE}, 3\text{LLFN, 7LSDAFILE, 3LFWB, BUFFER, 3LBFS, 400, 3LBCK, 3LYES})
\]

The file information table and the file environment table are to be constructed in the array named FILE. The file name (LFN) is SDAFILE. The buffer is to be placed in a 400-word array BUFFER. 3LBCK, 3LYES selects the block checksumming option.

Keywords and symbolic options, such as YES and NO, are passed as L format Hollerith constants.

For example:

\[
\begin{align*}
\text{3LFWB} & \quad \text{keywords} \\
\text{3LBCK} & \quad \text{keywords} \\
\text{3LYES} & \quad \text{symbolic options} \\
\text{2LNO} & \quad \text{symbolic options}
\end{align*}
\]

Numeric parameters must be integer variables or integer constants.

**UPDATING FILE INFORMATION TABLE**

After the file information table is created, it can be updated by calls to the subroutine STOREF.

\[
\begin{array}{c}
\text{CALL STOREF (fit,keyword,value)} \\
\text{fit} & \quad \text{Array where the file information table was created.} \\
\text{keyword} & \quad \text{File information table field.} \\
\text{value} & \quad \text{Value to be placed in the field.}
\end{array}
\]

Example:

\[
\text{CALL STOREF (FILE, 2LRL, 250)}
\]

Sets record length in the array FILE to 250 characters.
Contents of file information table fields can be accessed by using the integer function IFETCH.

IFETCH (fit,keyword)

fit            Name of the array containing file information table.
keyword        Name of the field.

If the keyword is a one-bit field, the result is returned in the sign bit and can be sensed by a positive-negative check; otherwise, it is returned right justified with zero fill.

Example:

M=IFETCH (FILE,2RL)

The record length is returned to the function IFETCH and replaces the value of M.

FILE COMMANDS

After the file information table is created, file processing commands can be issued. (FORTRAN file processing commands correspond to Record Manager macros of the same name.)

The first command must be OPENM, and the last CLOSEM. File command calls have positional parameters. If trailing parameters are omitted, the current value in the file information table will be used. However, no other parameters may be omitted; if the current value in the file information table is to be used, it must be specified. For example:

CALL PUT (fit,wsa,rl,ka/wa,kp,pos,ex)

If rl and the following parameters are to be specified, the parameter wsa cannot be omitted even if its value does not change, but ex could be omitted if the current value is to be used.

In the following calls, when two parameters occur in one position, for example ka/wa in CALL PUT, the first parameter applies to indexed sequential or direct access files, and the second to word addressable or sequential files.

In the following description of the file commands, fit is the name of an array containing the file information table.
OPENM prepares a file for processing. Each file must be opened before processing.

\begin{itemize}
  \item**pd** Processing direction established when file is opened:
    \begin{itemize}
      \item INPUT Read only
      \item OUTPUT Write only
      \item I-O Read and write
      \item NEW Indexed sequential or direct access file to be created (write only)
    \end{itemize}
  \item**of** Open flag specifies position of file when it is opened:
    \begin{itemize}
      \item R Rewind: file is rewound before any other open procedures are performed.
      \item N No file positioning is done before other open procedures.
      \item E File is positioned immediately before end of information to allow extensions to a mass storage file.
    \end{itemize}
\end{itemize}

Terminates processing.

GET reads a record from an input/output device and delivers it to the user’s record area.

\begin{itemize}
  \item wsa Address of user’s record area.
  \item ka Address of user’s key area for direct access or indexed sequential record to be read.
  \item wa Word address on file where reading is to start.
\end{itemize}
kp Beginning character position of key within ka. Key positions are ordered from left to right (0-9).

mkl Major key length on indexed sequential files.

ex Address of exit routine to be entered when an error occurs (word addressable, indexed sequential or direct access files). The value of ex must not be zero.

dx Address of end of data routine for sequential files.

rl Record length in characters.

```
CALL PUT (fit,wsa,rl,ka/wa,kp,pos,ex)
```

PUT places a record in a file.

pos Specifies relative position of record for duplicate key processing.

wsa,rl,ka,wa,kp,ex are the same as for GET.

```
CALL GETN (fit,wsa,ka,ex)
```

GETN accesses the next record on the file.

```
CALL DLTE (fit,ka/wa,kp,pos,ex)
```

DLTE removes a record from a file.

wa Word address of record to be deleted.

pos Specifies the last referenced (current) record will be deleted. Applies only when duplicate key processing is allowed.
CALL REPLC (fit, ws, rl, ka, kp, pos, ex)

REPLC replaces an existing record with a record from the user's record area.

pos    Specifies the last referenced (current) record will be replaced. Applies only when duplicate key processing is allowed.

CALL CHECK (fit)

CHECK determines whether input/output operations on a file are complete and upon completion returns control.

CALL SKIP (fit, tcount)

Repositions a file.

count    Number of logical records to be skipped: positive for a forward skip, negative for a backward skip.

CALL SEEKF (fit, ka, kp, mk, ex)

SEEKF allows central memory processing to overlap input/output operations.

CALL WEOR (fit, lev)

WEOR terminates a section and an S type record.

lev    Level number (any octal value 0 to 16) to be appended if record type is S; default is 00.
CALL WTMK (fit)

Writes a tape-mark.

CALL ENDFILE (fit)

Writes an end of partition.

CALL REWIND (fit)

REWIND positions a tape file to the beginning of the current volume. It positions a mass storage file to the beginning of information.

CALL GETP (fit, wsaw, ptr1, 4LSKIP, dx)

GETP retrieves partial records; it may be used to retrieve an arbitrary amount of data from a record.

- wsa: Address of user's record area to receive the record.
- ptr1: Partial transfer length. Number of characters to be transferred.
- 4LSKIP: Record Manager advances to next record before retrieving data.
- dx: Address of end-of-data routine.
CALL PUTP (fit,wsa,ptl,rl,ex)

Writes a portion of a record.

wsa Address of user’s record area from which the record portion will be taken.

ptl Same as GETP.

rl Record length in characters (required only for U, W, and R type records).

ex Address of error routine.

ERROR CHECKING

FORTRAN/Record Manager routines perform limited error checking to determine whether the call can be interpreted, but actual parameter values are not checked.

The following error conditions are detected, and a message appears in the dayfile:

FIT ADDRESS NOT SPECIFIED

Array name was not specified.

FORMAT ERROR

Parameters were not paired (FILExx), or required parameters were not specified (STOREF. IFETCH or SKIP).

UNDEFINED SYMBOL

A file information table field mnemonic or symbolic option was specified incorrectly: for example, an incorrect spelling, or the of parameter in OPENM was not specified as R, N or E.

Example of error message:

ERROR IN STOREF CALL

UNDEFINED SYMBOL IMPUT
MASS STORAGE INPUT/OUTPUT

Mass storage input/output subroutines allow the user to create, access, and modify multi-record files on a random basis without regard for their physical position or internal structure. A random file can reside on any mass storage device for which Record Manager word addressable file organization is defined. Each record in the file may be read or written at random without logically affecting the remaining file contents. The length and content of each record is determined by the user.

Six object time input/output subroutines control the transfer of records between central memory and mass storage. These routines employ the word addressable feature available through Record Manager (refer to Record Manager Reference Manual and 7000 SCOPE Reference Manual for details of this feature).

```
7
CALL OPENMS (u,ix,lngh,t)
```

OPENMS opens the mass storage file and informs Record Manager that it is a random (word addressable) file. The array specified in the call arguments is automatically cleared to zeros. If an existing file is being reopened, the master index is read from mass storage into the index array.

- **u**  Unit designator
- **ix** First word address in central memory of the array which will contain the index
- **lngh** Length of index
  - for a number index, \( lngh \geq (\text{number of records in file}) + 1 \)
  - for a name index, \( lngh \geq 2^x(\text{number of records in file}) + 1 \)
- **t**  
  - \( t = 0 \) file is referenced through a number master index
  - \( t = 1 \) file is referenced through a name master index

Example:

```
DIMENSION I(11)
CALL OPENMS (5,I,11,0)
```

Prepares for random input/output on unit 5 with an 11-word master index of the number type. If the file already exists, the master index is read into memory starting at address I.
CALL READMS (u,fwa,n,k)

Transmits data from mass storage to central memory.

u    Unit designator
fwa  Address in central memory of first word of record
n    Number of 60-bit central memory words in the record to be transferred
k    Number index: $k = 1 \leq k \leq \text{Length} - 1$
     Name index: $k = \text{any 60-bit quantity except } \pm 0$

Example:

CALL READMS (3,DATAMOR,25,2)

CALL WRITMS (u,fwa,n,k,r,s)

Transmits data from central memory to the selected mass storage device.

u, fwa, n, k are the same as for READMS.

r    $r = 1$ rewrite in place. Unconditional request; fatal error occurs if new record length exceeds old record length.
     $r = -1$ rewrite in place if space available, otherwise write at end of information
     $r = 0$ no rewrite; write normally at end of information

The default value for $r$ is 0 (normal write). The $r$ parameter can be omitted if the $s$ parameter is omitted.

s    $s = 1$ write sub-index marker flag in index control word for this record
     $s = 0$ do not write sub-index marker flag in index control word for this record

Default value is 0 if $s$ is omitted.

The $s$ parameter is included for future random file editing routines. Current routines do not test the flag, but the user should include this parameter in new programs when appropriate to facilitate transition to a future edit capability.

Example:

CALL WRITMS (3,DATA,25,6,1)
CALL STINDX (u,i,m,lnth,t)

STINDX selects a different array to be used as the current index to the file. The call permits a file to be manipulated with more than one index. For example, when the user wishes to use a sub-index instead of the master index, he calls STINDX to select the sub-index as the current index. The STINDX call does not cause the sub-index to be read or written; that task must be carried out by explicit READMS or WRITMS calls. It merely updates the internal description of the current index to the file.

u, ix, lnth and t are the same as OPENMS.

Examples:

DIMENSION SUBIX (10)
CALL STINDX (3, SUBIX, 10, 0)

DIMENSION MASTER (5)
CALL STINDX (2, MASTER, 5)

CALL CLOSMS (u)

The CLOSMS call is optional since its function is identical to that performed automatically by the FORTRAN object time routine SYSTEM when the run terminates. (SYSTEM and CLOSMS both write the master index from central memory to the file, and close the file.) CLOSMS is provided so that a file can be returned to the operating system before the end of a FORTRAN run, or to preserve a file created by an experimental job that may subsequently abort, or for other special circumstances.

Example:

CALL CLOSMS (2)

ACCESSING A RANDOM FILE

Random file manipulations differ from conventional sequential file manipulations. In a sequential file, records are stored in the order in which they are written, and can normally be read back only in the same order. This can be slow and inconvenient in applications where the order of writing and retrieving records differ and, in addition, it requires a continuous awareness of the current file position and the position of the required record. To remove these limitations, a randomly-accessible file capability is provided by the mass storage input/output subroutines.

In a random file, any record may be read, written or rewritten directly, without concern for the position or structure of the file. This is possible because the file resides on a random-access rotating mass storage device that can be positioned to any portion of a file. Thus, the entire concept of file position does not apply to a
random file. The notion of rewinding a random file is, for instance, without meaning.

To permit random accessing, each record in a random file is uniquely and permanently identified by a record key. A key is an 18- or 60-bit quantity, selected by the user and included as a READMS or WRITMS call parameter. When a record is first written, the key in the WRITMS call becomes the permanent identifier for that record. The record can be retrieved later by a READMS call that includes the same key, and it can be updated by a WRITMS call with the same key.

When a random file is in active use, the record key information is kept in an array in the user's field length. The user is responsible for allocating the array space by a DIMENSION, type or similar array declaration statement, but must not attempt to manipulate the array contents. The array becomes the directory or index to the file contents. In addition to the key data, it contains the word address and length of each record in the file. The index is the logical link that enables the mass storage subroutines, in conjunction with Record Manager, to associate a user call key with the hardware address of the required record.

The index is maintained automatically by the mass storage subroutines. The user must not alter the contents of the array containing the index in any manner; to do so may result in destruction of the file contents. (In the case of a sub-index, the user must clear the array before using it as a sub-index; and read the sub-index into the array if an existing file is being reopened and manipulated. However, individual index entries should not be altered.)

In response to an OPENMS call, the mass storage subroutines automatically clear the assigned index array. If an existing file is being reopened, the mass storage subroutines will locate the master index in mass storage and read it into this array. Subsequent file manipulations make new index entries or update current entries. When the file is closed, the master index is written from the array to the mass storage device. When the file is reopened, by the same job or another job, the index is again read into the index array space provided, so that file manipulation may continue.

INDEX KEY TYPES

There are two types of index key, name and number. A name key may be any 60-bit quantity except +0 or -0. A number key must be a simple positive integer, greater than 0 and less than or equal to (Inghth - 1). The user selects the type of key by the (t) parameter. The key type selection is permanent. There is no way to change the key type, because of differences in the internal index structure. If the user should inadvertently attempt to reopen an existing file with an incorrect index type parameter, the job will be aborted. (This does not apply to sub-indexes chosen by STINDX calls, proper index type specification is the sole reponsibility of the user.) In addition, key types cannot be mixed within a file. Violation of this restriction may result in destruction of a file.

The choice between name and number keys is left entirely to the user. The nature of the application may clearly dictate one type or the other. However, where possible, the number key type is preferable. Job execution will be faster and less central memory space will be required. Faster execution occurs because it is not necessary to search the index for a matching key entry (as is necessary when a name key is used). Space is saved due to the smaller index array length requirement.
Example:

PROGRAM MS1 (TAPE3)

C CREATE RANDOM FILE WITH NUMBER INDEX.

DIMENSION INDEX(11), DATA(25)
CALL OPENMS (3, INDEX, 11, 0)

DO 99 NRKEY=1, 10
C
C
C (GENERATE RECORD IN ARRAY NAMED DATA.)
C
C
99 CALL WRITMS (3, DATA, 25, NRKEY)

STOP
END

PROGRAM MS2 (TAPE3)

C MODIFY RANDOM FILE CREATED BY PROGRAM MS1.
C NOTE LARGER INDEX BUFFER TO ACCOMMODATE TWO NEW
C RECORDS.

DIMENSION INDEX(13), DATA(25), DATAMOR(40)
CALL OPENMS (3, INDEX, 13, 0)

C READ 8TH RECORD FROM FILE TAPE3.
CALL READMS (3, DATA, 25, 8)
C
C
C (MODIFY ARRAY NAMED DATA.)
C
C
C WRITE MODIFIED ARRAY AS RECORD 8 AT END OF
C INFORMATION IN THE FILE
CALL WRITMS (3, DATA, 25, 8)

C READ 6TH RECORD.
CALL READMS (3, DATA, 25, 6)
C
C
C (MODIFY ARRAY.)
C
C

C REWRITE MODIFIED ARRAY IN PLACE AS RECORD 6.
   CALL WRITMS (3,DATA,25,6,1)

C READ 2ND RECORD INTO LONGER ARRAY AREA.
   CALL READMS (3,DATAMOR,25,2)
C
   (ADD 15 NEW WORDS TO THE ARRAY NAMED DATAMOR.)
C
C
C CALL FOR IN-PLACE REWRITE OF RECORD 2. IT WILL
C DEFAULT TO A NORMAL WRITE AT END-OF-INFORMATION
C SINCE THE NEW RECORD IS LONGER THAN THE OLD ONE,
C AND FILE SPACE IS THEREFORE UNAVAILABLE.
   CALL WRITMS (3,DATAMOR,40,2,-1)

C READ THE 4TH AND 5TH RECORDS.
   CALL READMS (3,DATA,25,4)
   CALL READMS (3,DATAMOR,25,5)
C
   (MODIFY THE ARRAYS NAMED DATA AND DATAMOR.)
C
C
C WRITE THE ARRAYS TO THE FILE AS TWO NEW RECORDS.
   CALL WRITMS (3,DATA,25,11)
   CALL WRITMS (3,DATAMOR,25,12)

STOP
END

PROGRAM MS3 (TAPE7)

C CREATE A RANDOM FILE WITH NAME INDEX.

   DIMENSION INDEX(9), ARRAY(15,4)
   DATA REC1,REC2/?HRECORD,?RECORD2/}
C
C
C (GENERATE DATA IN ARRAY AREA.)
C
C
C WRITE FOUR RECORDS TO THE FILE. NOTE THAT
C KEY NAMES ARE RECORD(N).
    CALL WRITMS (7,ARRAY(1,1),15,REC1)
    CALL WRITMS (7,ARRAY(1,2),15,REC2)
    CALL WRITMS (7,ARRAY(1,3),15,7RRECORD3)
    CALL WRITMS (7,ARRAY(1,4),15,≠RECord4≠)

C CLOSE THE FILE.
    CALL CLOSMS (7)

STOP
END

MULTI-LEVEL FILE INDEXING

When a file is opened by an OPENMS call, the mass storage routines clear the array specified as the index area, and if the call is to an existing file, locates the file index and reads it into the array. This creates the initial or master index.

The user can create additional indexes (sub-indexes) by allocating additional index array areas, preparing the area for use as described below, and calling the STINDX subroutine to indicate to the mass storage routine the location, length and type of the sub-index array. This process may be chained as many times as required, limited only by the amount of central memory space available. (Each active sub-index requires an index array area.) The mass storage routine uses the sub-index just as it uses the master index; no distinction is made.

A separate array space must be declared for each sub-index that will be in active use. Inactive sub-indexes may, of course, be stored in the random file as additional data records.

The sub-index is read from and written to the file by the standard READMS and WRITMS calls, since it is indistinguishable from any other data record. Although the master index array area is cleared by OPENMS when the file is opened, STINDX does not clear the sub-index array area. The user must clear the sub-index array to zeros. If an existing file is being manipulated and the sub-index already exists on the file, the user must read the sub-index from the file into the sub-index array by a call to READMS before STINDX is called. STINDX then informs the mass storage routine to use this sub-index as the current index. The first WRITMS to an existing file using a sub-index must be preceded by a call to STINDX to inform the mass storage routine where to place the index control word entry before the write takes place.

If the user wishes to retain the sub-index, it must be written to the file after the current index designation has been changed back to the master index, or a higher level sub-index by a call to STINDX.†

†Since the file is closed automatically at job termination, it is no longer necessary as it was under previous versions of FORTRAN Extended, for the user to reset the master index before closing the file.
INDEX TYPE

MASTER INDEX

The master index type for a given file is selected by the t parameter in the OPENMS call when the index is created. The type cannot be changed after the file is created; attempts to do so by reopening the file with the opposite type index are treated as fatal errors.

SUB-INDEX

The sub-index type can be specified independently for each sub-index. A different sub-index name/number type can be specified by including the t parameter in the STINDEX call. If t is omitted, the index type remains the same as the current index. Intervening calls which omit the t parameter do not change the most recent explicit type specification. The type remains in effect until changed by another STINDEX call.

STINDEX cannot change the type of an index which already exists on a file. The user must ensure that the t parameter in a call to an existing index agrees with the type of the index in the file. Correct sub-index type specification is the responsibility of the user; no error message is issued.

Example:

```plaintext
PROGRAM MS4 (TAPE2)

C   GENERATE SUBINDEXED FILE WITH NUMBER INDEX. FOUR
C   SUBINDEXES WILL BE USED, WITH NINE DATA RECORDS
C   PER SUBINDEX, FOR A TOTAL OF 36 RECORDS.

   DIMENSION MASTER(5), SUBIX(10), RECORD(50)
   CALL OPENMS (2,MASTER,5,0)

   DO 99 MAJOR=1,4

C   CLEAR THE SUBINDEX AREA.
   DO 77 I=1,10

77   SUBIX(I)=0

C   CHANGE THE INDEX IN CURRENT USE TO SUBIX.
   CALL STINDEX (2,SUBIX,10)

C   GENERATE AND WRITE NINE RECORDS.
   DO 88 MINOR=1,9

C

C
```

III-7-8

60305600 A
C WRITE A RECORD.
88 CALL WRITMS (2, RECORD, 50, MINOR)

C CHANGE BACK TO THE MASTER INDEX.
CALL STINDX (2, MASTER, 5)

C WRITE THE SUBINDEX TO THE FILE.
CALL WRITMS (2, SUBIX, 10, MAJOR, 0, 1)

99 CONTINUE

C READ THE 5TH RECORD INDEXED UNDER THE 2ND SUBINDEX.
CALL READMS (2, SUBIX, 10, 2)
CALL STINDX (2, SUBIX, 10)
CALL READMS (2, RECORD, 50, 5)
C
C
C (MANIPULATE THE SELECTED RECORD AS DESIRED.)
C
C
STOP
END

CALL STINDX (9,COUNTY,501)
CALL READMS (9,CITY,501,≠SANTACLAURA≠)
CALL STINDX (9,CITY,501)
CALL READMS (9,ZIP,100,≠SUNNYVALE≠)
PRINT 12, ZIP

CALL STINDX (9,STATE,101)

STOP
END
ERROR MESSAGES

Random file processing errors are fatal; the job terminates and one of the following error messages is printed:

97 INDEX NUMBER ERR
   The index number key is negative, zero, or greater than the index buffer length minus one.

98 FILE ORGANIZATION OR RECORD TYPE ERR
   During the initial OPENMS call, mass storage routines set the file organization as word addressable (FO=WA) and the record type to W (RT=W). A conflicting file organization or record type was specified in an external subroutine call or FILE control card.

99 WRONG INDEX TYPE
   An attempt was made to open an existing file with the wrong index type parameter. File index type is permanently determined when a file is created.

100 INDEX IS FULL
   WRITMS was called with a name index key, and the end of the index buffer occurred before a match was found. Either the name key is in error, or the buffer must be lengthened.

101 DEFECTIVE INDEX CONTROL WORD
   This message may occur for either of two reasons:
   1. An OPENMS for an existing file found the master index control word has been destroyed. Since this word was properly set when the file was last closed, the user should check for an external cause of file destruction.
   2. A READMS or WRITMS call has encountered a defective index control word. Check for an improperly cleared sub-index array, for a program sequence that writes into an index array (other than the required initial zeroing) or for an external cause of file destruction.

102 RECORD LENGTH EXCEEDS SPACE AVAILABLE
   1. During an OPENMS call, not enough index buffer space was provided for the master index of an existing file.
   2. During a WRITMS call with in-place rewrite requested (r = +1), the new record length exceeded the old record length.

103 6RM/7DM I/O ERR NUMBER 000
   Record Manager has detected an error; the actual error number appears in the message. Refer to Record Manager Reference Manual to identify the source of the error.

104 INDEX KEY UNKNOWN
   No data record exists for the user’s index key. This error may be diagnosed for a READMS call or for a WRITMS call with rewrite requested (r = +1).
COMPATIBILITY WITH PREVIOUS MASS STORAGE ROUTINES

FORTRAN Extended mass storage routines and the files they create are not compatible with mass storage routines and files created under earlier versions of FORTRAN Extended. Major internal differences in the file structure were necessitated by adding the Record Manager interface. However, source programs are fully compatible. Any source program that compiled and executed successfully under earlier versions will do so under this version, provided that all file manipulations were and continue to be executed by mass storage routines.
The following information will be useful only to the assembly language programmer.

**REGISTER NAMES**

The compiler changes some legal FORTRAN names so that FORTRAN object code can be used as COMPASS input. When a two-character name begins with A, B, or X and the last character is 0 to 7, the compiler adds a currency symbol ($) to the name for the object code listing. (A0-A7, B0-B7, and X0-X7 represent registers to the COMPASS assembler which may be used by the FORTRAN Extended compiler).

**EXTERNAL PROCEDURE NAMES (PROCESSOR SUPPLIED)**

**CALL-BY-VALUE**

The name of a system supplied external procedure called by value is suffixed with a decimal point. The entry point is the symbolic name of the external procedure and a decimal point suffix. For example, EXP, COS, CSQRT.

The names of all external procedures called by value are listed in table 8-2 Basic External Functions, section 8, part 1. A procedure will not be called by value and the name will not be suffixed with a decimal point if it appears in an EXTERNAL statement or if the control card options T, D, or OPT = 0 are specified.

**CALL-BY-NAME**

The call-by-name entry point is the symbolic name of the external procedure with no suffix.

The call-by-name entry point consists of the symbolic name of the external procedure suffixed with a currency symbol. For example, ABSS MODS RANFS

External procedures called by name appear in section 8, part 1 under the heading Additional Utility Subprograms. Any name which appears in table 8-1 Intrinsic Functions or table 8-2 Basic External Functions will be called by name also if the control card options T, D, or OPT = 0 are specified or if it appears in an EXTERNAL statement.

Different entry points are required for many FORTRAN Extended and FORTRAN RUN common library routines because of the differences in calling sequences. The compiler makes the following changes to the names of external procedures:

SYSTEMC is changed to SYSTEME
OVERLAY is changed to OVERLA4
The following table shows the general form of a FORTRAN program unit. Statements within a group may appear in any order, but groups must be ordered as shown. Comment lines can appear anywhere within the program.

<table>

</tbody>
</table>

The following description of the arrangement of code and data within PROGRAM, SUBROUTINE and FUNCTION program units does not include the arrangement of data within common blocks because this arrangement is specified by the programmer. However, the diagram of a typical memory layout at the end of this section illustrates the position of blank common and labeled common blocks.
SUBROUTINE AND FUNCTION STRUCTURE

The code within subprograms is arranged in the following blocks (relocation bases) in the order given.

START.  Code for the primary entry and for saving A0

VARDIM.  Address substitution code and any variable dimension initialization code

ENTRY.  Either a full word of NO's or nothing

CODE.  Code generated by compiling:

Executable statements

Parameter lists for external procedure references within the current procedure

Storage statements

DO loops and optimizing temporary use

Storage for simple variables, FORMAT statements, and program constants

Storage for arrays other than those in common

Storage for Hollerith constants

One local block for each dummy argument in the same order as they appear in the subroutine statement, to hold tables used in address substitution for processing references to dummy arguments
**MAIN PROGRAM STRUCTURE**

**START.**
Input/output file buffers and a table of file names specified in the program statement

**CODE.**
Transfer address code plus the code specified for the subroutine and function CODE. block

**DATA.**
**DATA..**
**HOL.**
Same as SUBROUTINE and FUNCTION structure

**MEMORY STRUCTURE**

Memory is not cleared, and subprograms are loaded as they appear in the input file starting at the program's reference address (RA) + 100B, toward the user's field length (FL). RA to RA + 100B is the communication region used by the operating system. Labeled common blocks are loaded prior to the subprogram in which they are first referenced. Library routines are loaded immediately after the last subprogram and are followed by blank common.

Typical memory layout:

```
RA

Communication Region

RA + 100B

Common block ABLE

PROGRAM TEST
includes I/O buffer area

SUBROUTINE SUB

SYSTEM$
OUTPTC=
KODERS$
SIN.$
GETFIT$

Blank Common

FL
```
Subprograms written in COMPASS assembly language can be intermixed with FORTRAN coded subprograms in the source deck. COMPASS subprograms must begin with a card containing the word IDENTb, in columns 11-16, and terminate with a card containing the word ENDb, in columns 11-14 (b denotes a blank). Columns 1-10 of the IDENT and ENDb cards must be blank.

ENTRY POINT

The entry point of a subprogram (for reference by an RJ instruction) is preceded by two words. The first is a trace word for the subprogram; it contains the subprogram name in left justified display code (blank filled) in the upper 42 bits and the subprogram entry address in the lower 18 bits. The second word is used to save the contents of A0 upon entry to the subprogram. The subprogram must restore A0 upon exit.

Trace word:  VFD  42/name,  18/entry address
A0 word:    DATA  0
Entry point: DATA  0

CALL BY NAME SEQUENCE

When the FORTRAN compiler encounters a reference to an external subprogram, subroutine, or function, the following calling sequence is generated:
SA1  Argument list (if parameters appear)
+  RJ  Subprogram name
-VFD  12/line number, 18/trace word address
       line number  Source line number of statement containing the reference
       trace word  Address of the trace word for the calling routine
       address

Arguments in the call must correspond with the argument usage in the called routine, and they
must reside in the same level.

The argument list consists of consecutive words of the form:

VFD 60/address of argument

followed by a zero word.

The sign bit will be set in the argument list for any argument entry address which is LCM or ECS.

CALL BY VALUE SEQUENCE

The compiler generates a call-by-value code sequence for references to external library functions if the
function name does not appear in an EXTERNAL statement and the D, T, or OPT=0 options on the FTN
control card are not specified. The name of any library function called by value or generated in line must
appear in an EXTERNAL statement in the calling routine if the call-by-name calling sequence is required
(section 8, part 1 lists the library functions called by value and generated in-line).

The call-by-value code sequence consists of code to load the argument addresses into X1 through X4,
followed by an RJ instruction to the function. The second register loaded for a double precision or complex
argument contains the least significant or imaginary part of the argument.
LIBRARY ENTRY POINT NAMES

If a library function which can be called by value is overridden by a routine coded in COMPASS, the COMPASS routine must use the library function name with a period appended as the entry point name (e.g. SIN.) to use the call-by-value calling sequence.

If the library function name which can be called by value appears in an EXTERNAL statement in the calling program, the call-by-name calling sequence is generated. For call-by-name entry points, the COMPASS routine must use the library name with S appended (e.g. SINS)

CONTROL RETURN

The COMPASS subprogram must restore the initial contents of A0 upon returning control to the calling subprogram. When the COMPASS subprogram is entered through a function reference, the result of that function must be in X6, or in X6 and X7 with the least significant or imaginary part of the double precision or complex result appearing in X7.

For a subprogram with no arguments, the calling sequence is:

```
+ RJ  Subprogram name
- VFD 12/line number, 18/trace word address
```

where the trace word is of the form

```
VFD 42/7H routine name, 18/entry address
```
Example:

The following COMPASS subprogram which returns the field length of a FORTRAN program, can be referenced as either a subroutine or a function. In the first example, the field length is returned to the argument I in the CALL statement, and in the second example, it is returned as the value of the function IGETFL as well as the argument I.

1.

```
PROGRAM FL (OUTPUT)
    CALL IGETFL(I)
    PRINT 1, I, I
1 FORMAT (* OCTAL FIELD LENGTH = *05,* DECIMAL FIELD LENGTH = *I6)
END
```

2.

```
PROGRAM FL (OUTPUT)
    PRINT 1, Z FIELD LENGTH = *, IGETFL(I)
1 FORMAT (2A10, I6)
END
```

COMPASS SUBPROGRAM

<table>
<thead>
<tr>
<th>IDENT</th>
<th>IGETFL</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENTRY</td>
<td>IGETFL</td>
</tr>
</tbody>
</table>

RA.FL  EQU  76B  — Location 76 contains the field length of the FORTRAN program

IGETFL  BSSZ  1
SA2    RA.FL
BX6    X2  — Field length is moved to X6 (function results must be in X6)
SA6    X1
EQ     IGETFL
END

The field length is stored at the address of the subroutine argument contained in X1.

Output:

```
OCTAL FIELD LENGTH = 70000  DECIMAL FIELD LENGTH = 20672
```
When a program is entered at an INTERCOM control point, INTERCOM associates the file names specified in the PROGRAM statement with the user's remote terminal device; and all references to these files are directed to the terminal.

If the SCOPE files INPUT and OUTPUT are connected, FORTRAN READ, WRITE, and PRINT statements can be used for terminal communication. The user can specify other files to be associated with the terminal with calls to CONNEC and DISCON.

INTERCOM terminal input/output is supported for formatted or NAMELIST input/output only.

A file can be connected to the terminal with the statement:

```
CALL CONNEC (fn)
```

If the file is already connected, the request is ignored. If the file has been used previously, but is not connected, this request clears the file's buffer, writes an end of file, and backspaces over it before the connection is performed.

A file is disconnected by the statement:

```
CALL DISCON (fn)
```

This request is ignored if the file is not connected. After a disconnect, the file is re-associated with its former device.

`fn internal file name:

- File designator, 1 to 99
- Display code file name, L format, left justified with zero fill
- Simple integer variable whose value is either of the above
Examples:

CALL CONNEC (3LEWT)

CALL DISCON (6)

K = 5
CALL DISCON(K)

J = 12
CALL CONNEC(J)

Any files listed in the PROGRAM statement can be connected or disconnected during program execution. An attempt to connect or disconnect an undefined file results in a fatal execution time error, and the job is terminated.

If execution diagnostics are to be sent to the terminal, the file OUTPUT must be declared in the PROGRAM statement and connected to the terminal.

Calls to CONNEC and DISCON are ignored when programs are not executed through an INTERCOM control point.
During a typical compilation and execution, the following listings are produced:

source program

reference map

core map

The compiler produces a reference map for each routine successfully compiled. In this map, the compiler generated addresses assume loading of program units starts at location 0. A description of the reference map appears in section 14, part 1.

A map is produced by the loader at load time. In this map, the user program starts at relative address 100. (The first 100 words, 0-99, serve as the communication region between the SCOPE operating system and the user program.) Refer to the Loader Reference Manual for details of the load map.

To find the address of a variable, add the address of the program unit, which appears in the load map, to the address of the variable which appears in the reference map.

All locations and addresses in the reference map and the core map are in octal.

For example.

<table>
<thead>
<tr>
<th>VARIABLES</th>
<th>SN</th>
<th>TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 A</td>

</tbody>
</table>
the address of the generated code of the variable I would be:

\[
\begin{array}{c}
2477 \\
+16 \\
2515 \\
\end{array}
\]

**DMPX.**

When a program does not compile or execute successfully, a partial dump is produced. A DMPX includes the contents of the registers, the first 100 words of the user’s field length (the communication region used by SCOPE), and the contents of the 100 (octal) words immediately preceding and immediately following the addresses where the job terminated.

1. **P** Address of program step to be executed next if job had not terminated
2. **RA** Reference address: absolute address where user’s field begins. All other addresses are relative to this address.
3. **FL** Field length of job
4. **EM** Default exit mode
5. **RE** Extended core storage reference address
6. **FE** Field length assigned to job in extended core storage
7. **MA** Address in SCOPE monitor routine used for linkage between SCOPE and user program
8. **Address registers**
9. **Contents of address registers**
10. **Index registers**
11. **Contents of index registers**
12. **Operand registers. X1-X5 contain operands used in calculations; registers X6 and X7 contain the results of calculations.**
13. **Contents of operand registers**
14. **Contents of locations specified in the A register. For example, items 8 and 9 show register A2 contains the address 002155, and item 14 shows the address A2 contains 1725 2420 2524 0000 0133.**
15. **Address of 60-bit word in central memory, followed by contents of that word (in octal)**
16. **Indicates that contents of previous locations are repeated up to but not including this location**

Definition of Call-By-Name and Call-By-Value I-7-8
Call-By-Name Code Sequence Generated III-10-1
Call-By-Name Entry-Point Name III-8-1
Call-By-Value
Definition of Call-By-Name and Call-By-Value I-7-8
Call-By-Value Entry-Point Name III-8-1
Call-By-Value Code Sequence Generated III-10-2
CALL OVERLAY
CALL OVERLAY Statement I-12-5
Carriage
Carriage or Printer Control Characters I-9-2, I-10-32
Character-Set
Source Language Character-Set I-1-1
Character-Sets III-1-1
CHECK
File Processing Commands REPLC, CHECK, SKIP, SEEKF, WEOR III-6-6
Checking Operators
Checking Operators in STORES Statement I-13-11
CIRCLE
Sample Program CIRCLE II-1-35
CLOSEM
File Processing Commands OPENM, CLOSEM, GET III-6-4
CLOSMS
STINDX and CLOSMS III-7-3

Index-2 60305600 A
Color
Color Codes, Blue Non-ANSI, Green 6000 Series, and Red 7600 iv
Color Codes, Green CYBER-70 Models 72, 73 and 74, Red CYBER 70 Model 76 iv
Columns
Columns 73-80 I-1-2
COME
Sample Program COME II-1-11
Comma
Format Field Separators; Slash and Comma I-10-7
Comments
Comments I-1-2
COMMON
Definition of COMMON Statement I-6-8
EQUIVALENCE and COMMON I-6-16
Transferring Program and Subprogram Values through COMMON I-7-17
COMMON Blocks and EQUIVALENCE Classes in Reference Map I-14-12
COMPASS
Renaming Conventions for Object Code Used as COMPASS Input III-8-1
Intermixed COMPASS Subprograms III-10-1
COMPASS Subprogram Entry-Point III-10-1
Sample Intermixed COMPASS Subprogram III-10-4
Compilation
Compilation Diagnostics or Error Messages III-2-1
Compilation and Execution Listings III-12-1
Complex
Complex Variables I-2-11
Definition of Integer, Real and Complex Type Statements I-6-2
Complex Constant I-2-4
Complex Conversion in Assignment Statements I-4-4
Computed
Computed GO TO Statement I-5-2
Constants
Constants I-2-1
Continuation
Continuation Lines I-1-2
Debug Continuation Card I-13-4
CONTINUE
CONTINUE I-5-14
Control Card
FORTRAN Control Card I-11-1
FTN Control Card Parameters I-11-1
Cross
Symbolic or Cross Reference Map I-14-1
CYBER-70
Color Codes, Green CYBER-70 Models 72, 73 and 74, Red CYBER 70 Model 76 iv

D
Output of Double Precision Variables D Specification I-10-16
Input of Double Precision Variables D Specification I-10-17
DATA
Definition of DATA Statement I-6-21
Examples of Alternative Form of DATA Statement I-6-25
Data Conversion I-10-6
Data Cards
Format of Data Cards I-1-2
Debug
Example of Debug Statements Interspersed in Deck I-13-20
Example of External Debug Deck I-13-21
Example of Internal Debug Deck I-13-22
Example of External Debug Deck on Separate File I-13-23
DEBUG Statement I-13-24
File Name DEBUG I-13-30
Debugging
Debugging Facility I-13-1
Debug Deck
Debug Deck Structure I-13-19
Deck Structures
Sample Deck Structures III-13-1
Declaration
Specification or Declaration Statements I-6-1
DECODE
DECODE Statement I-9-18
Explanation of ENCODE and DECODE Statements II-1-19
Default Options
Default Options on Control Cards I-11-1
Definition
Definition of Integer, Real and Complex Type Statements I-6-2
Diagnostics
Compilation Diagnostics or Error Messages III-2-1
Execution Diagnostics or Error Messages III-2-14
DIMENSION
Definition of DIMENSION Statement I-6-6
DLTE
File Processing Commands PUT, GETN, DLTE III-6-5
DMPX.
Description of DMPX. III-12-2
DO
DO Statement I-5-8
DO Loop Maps I-14-10
Double
Double Precision Constant I-2-3
Double Precision Variables I-2-11
Double Precision and Logical Type Statements I-6-3
Output of Double Precision Variables D Specification I-10-16
Input of Double Precision Variables D Specification I-10-17
Double Precision
Real and Double Precision Conversion in Assignment Statements I-4-3
DO Implied
DO Implied Specification in Input-Output List I-10-2
Dummy Arguments
Dummy Arguments in Subprograms I-7-5
E
Output of Real Number with Exponent E Specification I-10-9
Input of Real Number with Exponent E Specification I-10-11
Scale-Factor with E and G Input-Output I-10-24
ENCODER
ENCODER Statement I-9-15
Explanation of ENCODE and DECODE Statements II-1-19
END
END I-5-15
END Statement in FUNCTION Subprogram I-7-6
END Statement in Overlay I-12-6
ENDFILE
ENDFILE I-9-7
Effect of ENDFILE on Various Record Types III-5-11
File Processing Commands WTMK, ENDFILE, REWND, GETP III-6-7

ENTRY
- Definition of ENTRY Statement I-7-20

Entry-Points
- Entry-Points in Reference Map I-14-2
- Call-By-Value Entry-Point Name III-8-1
- COMPASS Subprogram Entry-Point III-10-1
- Call-By-Name Entry-Point Name III-8-1

EOF
- EOF Function (Non-Buffered Input/Output) III-5-15

EQUIV
- Sample Program EQUIV II-1-9

EQUIVALENCE
- EQUIVALENCE Statement and Equivalence Group I-6-11
- EQUIVALENCE and COMMON I-6-16
- COMMON Blocks and EQUIVALENCE Classes in Reference Map I-14-12

Error
- Compilation Diagnostics or Error Messages III-2-1
- Execution Diagnostics or Error Messages III-2-14
- Non-Standard Error Recovery III-3-3
- FORTRAN/RECORD Manager Error Checking III-6-8
- Random File Processing Error Messages III-7-11

Errors
- Tracing Arithmetic Errors III-4-11
- MODE Errors III-4-8

ERRSET
- ERRSET III-5-17

Evaluation
- Evaluation of Expressions I-3-2

Execution
- Variable or Execution Time FORMAT Statements I-10-36
- Execution Diagnostics or Error Messages III-2-14
- Compilation and Execution Listings III-12-1

Exponentiation
- Exponentiation I-3-6

Expressions
- Arithmetic Expressions and Operators I-3-1
- Precedence of Operators for Evaluation of Expressions I-3-2
- Relational Expressions I-3-7
- Order of Dominance of Arithmetic Expressions I-3-5

Extended
- Definition of Extended Range of DO Loop I-5-8

EXTERNAL
- Definition of EXTERNAL Statement I-6-18
- Example of External Debug Deck I-13-21
- Example of External Debug Deck on Separate File I-13-23
- External References and Inline-Functions in Reference Map I-14-7

External Functions
- Basic External Functions I-8-6

F
- Output of Real Number F Specification I-10-13
- Input of Real Number F Specification I-10-14
- Scale Factor with F Input-Output I-10-23

File
- Definition of File III-5-1
- Block and Record Types on Record Manager FILE Control Card III-5-5
- FILE Card in Sample Deck III-5-7
File Information Table Calls FILESQ, FILEWA, FILEIS, FILEDA III-6-1
Updating File Information Table with STOREF III-6-2
FILEDA
File Information Table Calls FILESQ, FILEWA, FILEIS, FILEDA III-6-1
FILEIS
File Information Table Calls FILESQ, FILEWA, FILEIS, FILEDA III-6-1
Files
Labeled Files III-5-12
FILESQ
File Information Table Calls FILESQ, FILEWA, FILEIS, FILEDA III-6-1
FILEWA
File Information Table Calls FILESQ, FILEWA, FILEIS, FILEDA III-6-1
File Name
File Name Handling by SYSTEM III-3-6
Specifying File Name at Execution Time III-3-6
File Names in Reference Map 1-14-6
File Processing
File Processing Command III-6-3
Floating-Point
Floating-Point Representation Table III-4-4
FORMAT
Definition of FORMAT Statement I-10-5
Repeated FORMAT Specification I-10-31
Variable or Execution Time FORMAT Statements I-10-36
Formatted
Unformatted and Formatted WRITE Statements I-9-4
Formatted READ Statements I-9-5
FORTRAN
FORTRAN Control Card I-11-1
FORTRAN Record in FORMAT Specification I-10-29
FTN
FTN Control Card Parameters I-11-1
FUNCS
FUNCS Debug Statement E-13-8
FUNCTION
Definition of FUNCTION Subprogram I-7-6
FUNCTION Subprogram With Same Name as Library Function I-7-8
Functions
Intrinsic or Inline Functions I-8-1
Library Functions I-8-13
G
G Specification on Input and Output I-10-15
Scale Factor with E and G Input-Output I-10-24
GET
File Processing Commands OPENM, CLOSEM, GET III-6-4
GETN
File Processing Commands PUT, GETN, DLTE III-6-5
GETP
File Processing Commands WTMK, ENDFILE, REWND, GETP III-6-7
GOTO
GOTO Statements I-5-1
GOTOS
GOTOS Debug Statement I-13-15
Green
Color Codes, Blue Non-ANSI, Green 6000 Series, and Red 7600  iv
Color Codes, Green CYBER-70 Models 72, 73 and 74, Red CYBER 70 Model 76  iv
Group
   EQUIVALENCE Statement and Equivalence Group I-6-11
Group Name
   NAMELIST Statement and NAMELIST Group Name I-9-9

H
   Input-Output of Hollerith Fields Using H Specification I-10-25
Hollerith
   Hollerith Constant I-2-6
   Use of # # Hollerith String Delimiter in Expressions and I/O Lists I-2-7
   Octal and Hollerith Data in Variables I-2-11
   *** and ### Symbols Delineating Hollerith Field I-10-27
   Input-Output of Hollerith Fields Using H Specification I-10-25
   Hollerith Data Interpreted by STORES Statement I-13-14

I
   Integer Input-Output Using I Specification I-10-8
IF
   Arithmetic IF, Three Branch I-5-6
   Arithmetic IF, Two Branch I-5-6
   Logical IF, One Branch I-5-7
   Logical IF, Two Branch I-5-8
IFETCH
   Function IFETCH III-6-3
IMPLIED
   Definition of IMPLIED Statement I-6-3
Implied DO
   Array Transmission in Input-Output Lists Using Implied DO I-10-2
Indefinite
   Indefinite Result III-4-4
Index
   Index Keys Name and Number III-7-4
Indexing
   Multi-level File Indexing III-7-7
Inline
   Intrinsic or Inline Functions I-8-1
Inline Functions
   External References and Inline Functions in Reference Map I-14-7
Input-Output
   Input-Output Control Statements I-9-1
   Input-Output Lists I-10-1
   DO Implied Specification in Input-Output List I-10-2
   Object-Time Input-Output III-5-1
   Mass-Storage Input-Output Subroutines III-7-1
Integer
   Integer Constant I-2-1
   Integer and Real Variables I-2-10
   Definition of Integer, REAL and Complex Type Statements I-6-2
   Integer Input-Output Using I Specification I-10-8
   Integer Conversion in Assignment Statements I-4-2
INTERCOM
   FORTRAN INTERCOM INTERFACE III-11-1
Internal
   Example of Internal Debug Deck I-13-22
Interspersed
   Example of Debug Statements Interspersed in Deck I-13-20
Intrinsic
Intrinsic or Inline Functions I-8-1

IOCHEC
IOCHEC Function III-5-16

Keys
Index Keys Name and Number III-7-4

L
R and L Hollerith Constants I-2-8
L Specification on Input and Output I-10-22

LABEL
Object Time Subroutine LABEL III-5-12
Labeled
Labeled Files III-5-12
Labels
Statement Labels or Statement Numbers I-1-2
Statement and FORMAT Labels in Reference Map I-14-9

LCM
LCM and SCM Variables I-2-9
LCM Common Block in Overlay I-12-3

LEVEL
Definition of LEVEL Statement I-6-17
Levels
Levels in Debug Statements I-13-6

Library
FUNCTION Subprogram With Same Name as Library Function I-7-8
FORTRAN Library I-8-1
Library Subroutines I-8-9
Library Functions I-8-13

LIBS
Sample Program LIBS II-1-14

Linkage
Overlay Linkage and Creation of Overlays I-12-3

List
List Control Options on Control Cards I-11-2

Listings
Compilation and Execution Listings III-12-1

Logical
Logical Constants I-2-8
Logical Variables I-2-11
Logical Expressions I-3-9
Logical IF, One Branch I-5-7
Logical IF, Two Branch I-5-8
Double Precision and Logical Type Statements I-6-3
Precedence of Logical Operators .NOT., .AND., .OR. I-3-10
Logical and Masking Assignment I-4-5
Logical File III-5-1

Main Program
Main Program I-7-1

Map
Symbolic or Cross Reference Map I-14-1

MASK
Sample Program MASK II-1-6
Masking
   Masking Expressions I-3-13
   Logical and Masking Assignment I-4-5
Mass Storage
   Mass Storage Input-Output Subroutines III-7-1
   Mass Storage Routines, Compatibility with Previous Versions of FORTRAN III-7-12
Master Index
   Index Type; Master Index and Sub-Index III-7-8
Memory
   Program and Memory Structure III-9-1
MODE
   MODE Errors III-4-8
Multiple
   Multiple Assignment or Replacement I-4-6

Name
   Symbolic Name I-2-9
NAMELIST
   NAMELIST Statement and NAMELIST Group-Name I-9-9
   Arrays in NAMELIST I-9-13
   Namelist in Reference Map I-14-8
NOGO
   NOGO Debug Statement I-13-18
Non-Standard
   RETURNS-List, Non-Standard RETURN I-7-13
   Non-Standard Error Recovery III-3-3
.NOT.
   .NOT. in Masking Expressions I-3-15
   .NOT. in Logical Expressions I-5-12
   Precedence of Logical Operators .NOT., .AND., .OR. I-3-10
   Masking Operators .NOT., .AND., .OR. I-5-13

O
   Input of Octal Values 0 Specification I-10-17
   Output of Octal Values 0 Specification I-10-18
Object Time
   Object Time Input-Output III-5-1
Octal
   Octal Constant I-2-5
   Octal and Hollerith Data in Variables I-2-11
   Input of Octal Values 0 Specification I-10-17
   Output of Octal Values 0 Specification I-10-18
OFF
   OFF Debug Statement I-13-28
OPENM
   File Processing Commands OPENM, CLOSEM, GET III-6-4
OPENMS
   OPENMS III-7-1
Operators
   Arithmetic Expressions and Operators I-3-1
   Precedence of Operators for Evaluation of Expressions I-3-2
   Relational Operators I-3-7
   Precedence of Logical Operators .NOT., .AND., .OR. I-3-10
   Masking Operators .NOT., .AND., .OR. I-5-13
Optimization
   Optimization I-11-7
.OR.
Precedence of Logical Operators .NOT., .AND., .OR. I-3-10
Masking Operators .NOT., .AND., .OR. I-3-13
OUT
Sample Program OUT II-1-1
Overflow
Arithmetic Overflow and Underflow III-4-3
Overlay
Overlay Directive I-12-4
Overlays
Overlays I-12-1

P
Scale Factor P Specification I-10-22
Parity
Parity Error Detection III-5-17
PASCAL
Sample Program PASCAL II-1-22
PAUSE
PAUSE I-5-14
Physical Record
Physical Record III-5-1
PIE
Sample Program PIE II-1-17
PRINT
Definition of PRINT Statements I-9-2
Printer
Carriage or Printer Control Characters I-9-2, I-10-32
Procedure
Procedure Subprograms I-7-5
PROGRAM
Definition of PROGRAM Statement I-7-1
Program and Memory Structure III-9-1
Program-Unit
Definition of Program-Unit I-7-5
PRU
Physical Record Unit PRU III-5-1
Maximum PRU Size III-5-2
PUNCH
PUNCH Statements I-9-3
PUT
File Processing Commands PUT, GETN, DLTE III-6-5
PUTP
File Processing Command PUTP III-6-8

R
R and L Hollerith Constants I-2-8
Alphanumeric Input-Output R Specification I-10-21
Random
Default Conventions Random Files III-5-4
Accessing Random Files III-7-3
Random File Processing Error Messages III-7-11
Range
Definition of Extended Range of DO Loop I-5-8
READ
Formatted READ Statements I-9-5
Unformatted READ Statement I-9-6
READMS
    READMS and WRITMS  III-7-2
Real
    Real Constant  I-2-2
    Integer and Real Variables  I-2-10
    Definition of Integer, Real and Complex Type Statements  I-6-2
    Output of Real Number with Exponent E Specification  I-10-9
    Output of Real Number F Specification  I-10-13
    Real and Double-Precision Conversion in Assignment Statements  I-4-3
Record
    FORTRAN Record Length  I-9-2
    Definition of Record III-5-1
    Block and Record Types on Record Manager FILE Control Card  III-5-5
    FORTRAN Record in FORMAT Specification  I-10-29
Record Manager
    Block Record Formats Supported by Record Manager iii-5-2
    FORTRAN Record Manager Interface  III-6-1
Red
    Color Codes, Blue Non-ANSI, Green 6000 Series, and Red 7600  iv
    Color Codes, Green CYBER-70 Models 72, 73 and 74, Red CYBER 70 Model 76  iv
Reference
    Symbolic or Cross Reference Map  I-14-1
Relational
    Relational Expressions  I-3-7
    Relational Operators  I-3-7
    Evaluation of Relational Expressions  I-3-8
Renaming
    Renaming Conventions for Object Code Used as COMPASS Input  III-8-1
Repeated
    Repeated FORMAT Specification  I-10-31
Replacement
    Arithmetic Assignment or Replacement Statements  I-4-1
REPLC
    File Processing Commands REPLC, CHECK, SKIP, SEEKF, WEOR  III-6-6
RETURN
    RETURN  I-5-16
    RETURN Statement in SUBROUTINE Subprogram  I-7-13
    RETURNS List, Non-Standard RETURN  I-7-15
RETURNS List
    RETURNS List, Non-Standard RETURN  I-7-13
REWIND
    REWIND and BACKSPACE Statements  I-9-6
REWND
    File Processing Commands WTMK, ENDFILE, REWND, GETP  III-6-7
RLIST
    RLIST  I-11-8

Sample Program
    Sample Program ADD  II-1-19
    Sample Program B  II-1-4
    Sample Program CIRCLE  II-1-35
    Sample Program COME  II-1-35

    Sample Program LIBS  II-1-14
    Sample Program MASK  II-1-6
    Sample Program OUT  II-1-1
    Sample Program PASCAL  II-1-22
Sample Program PIE II-1-17
Sample Program VARDIM II-1-26
Sample Program VARDIM2 II-1-28
Sample Program X II-1-24
Scale Factor
Scale Factor P Specification I-10-22
SCM
LCM and SCM Variables I-2-9
SEEKF
File Processing Commands REPLC, CHECK, SKIP, SEEKF, WEOR III-6-6
Separator
$ Statement Separator I-1-2
Format Field Separators; Slash and Comm I-10-7
Sequential
Default Conventions Sequential Files III-5-3
SKIP
File Processing Commands REPLC, CHECK, SKIP, SEEKF, WEOR III-6-6
Slash
Format Field Separators; Slash and Comm I-10-7
/S Slash in FORMAT Specification I-10-29
Specification Subprogram
BLOCK-DATA or Specification Subprogram I-6-26
Specification or Declaration Statements I-6-1
Statement
Statement Column Numbers I-1-2
$ Statement Separator I-1-2
Statement Labels or Statement Numbers I-1-2
Statement Formats viii
Definition of Statement Function I-7-9
STINDX
STINDX and CLOSMS III-7-3
STOP
STOP I-5-15
STOREF
Updating File Information Table with STOREF III-6-2
STORES
STORES Debug Statement I-13-11
STRACE
STRACE I-13-30
Subprograms
Subprograms I-7-5
Utility Subprograms I-8-9
Sample Intermixed COMPASS Subprogram III-10-4
SUBROUTINE
Definition of SUBROUTINE Subprogram I-7-12
Library Subroutines I-8-9
Subscripts
Value and Content of Subscripts I-2-17
Sub-Index
Index Type; Master-Index and Sub-Index III-7-8
Symbolic
Symbolic or Cross Reference Map I-14-1
SYSTEM
SYSTEM Routine III-3-1
TAPEu
File Name TAPEu in PROGRAM Statement I-7-2
TRACE
TRACE Debug Statement I-13-16
Truth
Truth Table I-3-10
Type
Type of Arithmetic Expressions I-3-5
Type Conversion During Evaluation of Arithmetic Expressions I-3-5
TYPE Statements I-6-1
Definition of Integer, Real and Complex Type Statements I-6-2
Double Precision and Logical Type Statements I-6-3
Subscripted Symbolic Name in Type Specification I-6-5
T Specification
Column Selection Control T Specification I-10-34
Unary
Unary Addition and Subtraction I-3-2
Unconditional
Unconditional GO TO Statement I-5-2
Underflow
Arithmetic Overflow and Underflow III-4-3
Unformatted
Unformatted and Formatted WRITE Statements I-9-4
Unformatted READ Statement I-9-6
UNIT
UNIT Function (Buffered Input/Output) III-5-14
Unsubscribed
Unsubscripted Array Name I-2-13
Utility
Utility Subprograms I-8-9
VARDIM
Sample Program VARDIM II-1-26
VARDIM2
Sample Program VARDIM2 II-1-28
Variable
Variable or Execution Time FORMAT Statements I-10-36
Variables
Variables I-2-9
Typing of Variables I-2-10
Variables in Reference Map I-14-3
Variable Dimensions
Adjustable Dimensions or Variable Dimensions I-7-18
WEOR
File Processing Commands REPLC, CHECK, SKIP, SEEKF, WEOR III-6-6
WRITE
Unformatted and Formatted WRITE Statements I-9-4
WRITMS
READMS and WRITMS III-7-2
WTMK
File Processing Commands WTMK, ENDFILE, REWND, GETP III-6-7
X
X Specification I-10-24
Sample Program X II-1-24
63-Character
   CDC 63-Character Set  III-1-4
