Book 5

Executing the Program On-Line

Linking Loader
(LOADER)

DDT-10
PROGRAM LOADING AND LIBRARY FACILITIES

LINKING LOADER (LOADER) (Version 4043 and later)

The Linking Loader loads and links relocatable binary (.REL) programs generated by Macro-10 or
FORTRAN IV preparatory to execution and generates a symbol table in core for execution under the
Dynamic Debugging Technique program. It also provides automatic loading and relocation of Macro-
and FORTRAN-generated binary programs, produces an optional storage map, and performs loading and
library searching regardless of the input medium. Storage used by the Linking Loader is recoverable
after loading.

Requirements

Minimum Core: 3K
Additional Core: Automatically requests additional core from the
Monitor as required
Equipment: User teletype for control; one or more input
devices for binary programs to be loaded; output
device for loader map (optional); one system
device containing library files (optional).

NOTE

The LOADER as described herein loads and links pro-
grams assembled by the Macro Assembler, or compiled
by the FORTRAN Compilers. For those users who do
not wish to load FORTRAN programs (which require a
substantial portion of code within LOADER), a smaller
version of the LOADER, called 1KLOAD (although it
is actually larger than 1K), is available. 1KLOAD
may be generated from the same symbolic file as LOAD-
ER by setting the parameter K to some nonzero number
(e.g., K = 1).
Initialization

\texttt{.R \textsc{LOADER} core \textsc{.S}}

Loads the Linking Loader into core. The amount of core allocated is equal to 2K plus the core required by binary programs; core is optional.

\texttt{\textsc{.S}}

Indicates that the program is ready to receive a command.

Commands

General Command Format

\texttt{list-dev:filename.ext source-dev1:filename.ext,dev2:...source-n \$}

\texttt{list-dev:}

The device on which any storage maps or undefined globals are to be written.

- \texttt{LPT:} (line printer)
- \texttt{TTY:} (Teletype)
- \texttt{DTAn:} (DECTape)
- \texttt{DSK:} (disk)
- \texttt{MTAn:} (magnetic tape)

If the Teletype is to be assumed as the output device, omit

\texttt{list-dev:filename.ext -}

\texttt{source-dev:}

The device(s) from which the binary relocatable programs are to be loaded.

- \texttt{DSK:} (disk)
- \texttt{DTAn:} (DECTape)
- \texttt{MTAn:} (magnetic tape)
- \texttt{PTR:} (paper tape reader)

If more than one file is to be loaded from a magnetic tape, card reader, or paper tape reader, \texttt{dev:} is followed by a comma (or the device name or : can be repeated) for each file after the first.

\texttt{filename.ext (DSK: and DTAn: only)}

The \texttt{filename.ext} of each relocatable binary file to be loaded. If \texttt{.ext} is omitted, it is assumed to be \texttt{.REL}. If a search for \texttt{filename.REL} is unsuccessful, a second search for the same \texttt{filename} with the null extension is performed.

The \texttt{filename.ext} of the output listing file. If \texttt{.ext} is omitted, \texttt{.MAP} is used.

If the \texttt{filename .ext} of the output map file is omitted, MAPMAP.MAP is used. If only the extension is omitted, the extension MAP is used.

The storage map device is separated from the source device(s) by the left arrow symbol.
NOTES

Each time RETURN ( ) is typed, loading is performed for all files listed on that line.

Each time $ is typed, all remaining loading, library searches, and output operations are completed, and an exit is made to the monitor.

The source device, once stated, continues as the source device until a new source device or destination device is specified, or until $ is typed.

Files are loaded in the order they appear in the command string. The file requiring the largest COMMON area must be specified first in any loading operation.

When loading is terminated (by $ or switches /C, /G, or /R), the following steps are executed.

a. A FORTRAN library search is performed if any undefined globals remain (unless prevented by the /P switch).

b. If undefined globals still remain, they are listed on the teletype or other specified listing device.

c. The number of multiply defined globals (if any) and the number of undefined globals (if any) are printed on both the teletype and on the specified listing device (if given).

d. A Chain file, if requested, is written.

e. The loaded program is relocated down to the actual locations into which it is to be loaded.

f. The message

   "LOADER x+y: core x = low segment core; y = high segment core; if non-reentrant program y = 2K; if re-entrant, y = program high segment or Loader high segment, whichever is greater"

   is printed on the Teletype.

When an automatic library search is requested by /F, /G, or $, the following files will be searched in order:

a. JOBDAT
b. FORTRAN Library (LIB40 or LIB4)
c. JOBDAT
Since JOBDAT is searched after the FORTRAN Library, it is not necessary to include it as a portion of the FORTRAN Library. It is also searched prior to the FORTRAN Library so that users who do not require FORTRAN Library subroutines do not spend the time searching the Library. (The FORTRAN Library can be named LIB40 as on the PDP-10 or LIB4 as on the PDP-6; an attempt to find LIB40 is made first; if not found, an attempt to find LIB4 follows.)

Save and Execute Commands

After loading is completed, to write the loaded program onto an output device so that it can be executed at some future date without rerunning Linking Loader:

LOAD  
EXIT  
1C   

SAVE dev:filename.ext core

Loading is completed.
Automatic exit to the Monitor.

Write out the user's area of core onto the specified output device and, if the device is DTAn: or DSK: assign it the specified filename.ext. If .ext is omitted, .SAV is assumed.

The value for core may be given when the user wishes to run the program in more core than it will be saved in; this might be done to gain more space for dynamic allocation of buffers.

JOB SAVED
1C

Save operation completed. Core is unchanged and still contains loaded program. Automatic return is made to the Monitor.

START

Start execution of loaded program. Return is made to user's level.

EXIT
1C

User’s program execution is completed. Automatic return is made to the Monitor.

Examples

R LOAD

DSK:MARK1,MARK3,DTA3: SUBRTE
CALC,PTF: $2

LOAD 6+2K CORE
EXIT
1C

Run the Linking Loader.

Load and link the .REL files MARK1 and MARK3 from the disk, .REL files SUBRTE and CALC from DTA3, and one .REL file from the paper tape reader.

Link-loading is completed; and automatic return is made to the Monitor.
Write out the user's program as an executable program on the disk and call the file MARKET.DMP. Core assigned to the user remains unchanged.

NOTE

Saving a job is optional.

Save process is completed; an automatic return is made to the Monitor.

Begin execution of job.

Program execution is completed; automatic return is made to the Monitor.

Switches

Switches are used to:

a. Specify the types of symbols to be loaded or listed
b. Set the Library Search Mode
c. Load the Dynamic Debugging Technique (DDT) program
d. Clear and restart Linking Loader.

All switches are either preceded by a slash (/) or enclosed in parentheses.

Linking Loader Switch Options

<table>
<thead>
<tr>
<th>Switch</th>
<th>Meaning</th>
<th>Complement Switch</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>List all global symbols in storage map regardless of program length.</td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>(Loader feature switch DMNSW must have been set to nonzero when Loader was assembled for this switch to be available) Block transfer the loaded job's symbol table from its normal position at the top of core down to the first free location. Leave small amount of core (SYMPAT) between JOBSA and bottom of symbol table to allow for user-defined symbols. /B allows programs loaded with DDT to usefully run in as much core as is available without destroying the symbol table, and can be used with large programs which do little I/O to run in less core than needed to load and yet retain DDT and all symbols.</td>
<td>X†</td>
</tr>
</tbody>
</table>
## Linking Loader Switch Options

<tr>
<td>Z</td>
<td>Clear user's core area; reset the loader to its initial state; restore the teletype; restart loading. Terminates line.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

† indicates those switches set when Loader is in its initial state.

The effect of a switch on adjacently named files in the command string depends upon whether the switch is a status switch or an action switch.

**Status Switches** - The status switches A, I, J, L, N, O, P, Q, S, W, X set the Loader to a particular status and have an effect on the file in whose specification it appears and on any subsequently named files in the command string (unless the switch is reset). A file specification is terminated and processed when a comma, or a colon (if the previous delimiter was a colon), a RETURN, or $ is encountered.

*DTA5:RESID/S,/M  
Local symbols are loaded for this and any following files. A storage map is printed for this file.

*DTA5:RESID, M/S  
A storage map is printed for this file; however, local symbols are not loaded for this file since the /S switch appears outside the file specification.
Action Switches - The action switches B, C, D, E, F, G, H, M, R, T, U, V, Y request an immediate or file-independent action to be performed by the Loader and are not directly related to any specific file specification(s).

Chain Feature

The Chain feature is used to segment FORTRAN programs which are too large to be loaded into core as one unit. When switch /C or /R is specified, loading is terminated and a file acceptable to the Chain program is written.

Examples:  _DSK:CHNPGR -/R or _DATA:SEGF4 -/C

If .ext is omitted for the output Chain filename, .CHN is used.

The Chain file contains:

a. The contents to be loaded into JOB41, JOBDDT, JOBSA, JOBFF, and JOBSYM.

b. The data, beginning from the Chain address through the top of the core area used in loading.

The Chain address is set from JOBCHN as loaded; switch /C specifies the right half and switch /R specifies the left half. Location JOBCHN is loaded as follows: the right half contains the program break of the first FORTRAN IV BLOCK DATA program; the left half contains the program break of the first FORTRAN IV program. If switch /C or /R contains a nonzero numeric argument, this becomes the starting address of the loaded program. After the Chain file has been written correctly, the messages below are output to the teletype.

\[
\begin{align*}
\text{CHAIN} & \\
\text{EXIT} & \\
1 \ C
\end{align*}
\]

Examples

\[\text{R LOADER 6} \]
\[\text{D\_DATA:RESID, SUB1, SUB2, DTA3: COMPLX} \]

Run Linking Loader, and assign it 6K of core.

Load and link binary program files RESID.REL, SUB1.REL, and SUB2.REL from DTA5, and the file COMPLX.REL, DTA3.
Carriage return initiates loading.

\*F\*  
Force a premature search of LIB40 to resolve any undefined globals up to this point.

\*U\*  
List on the teletype (since no output device was specified in the first command line) all globals which are still undefined.

? ?SUB4A \*UNDEFINED GLOBALS\*  
Undefined global and location containing instruction which calls it are listed.

?OTA5:SUB4\*  
Knowing that the undefined global is in the binary program file SUB4, the user requests that it be loaded also.

?LPT:\*M=  
Check if undefined global has now been resolved.

?LOAD  
All globals are defined; print storage map on the line printer and exit to the Monitor.

Use of /E Switch:

\*R LOADER  
\*D5K:PRG41:PRG2/E  
LOAD 5+2K CORE  
...program execution occurs here...

(EXIT)  

Diagnostic Messages

### Monitor Commands

Loading of relocatable binary files can be performed by use of the LOAD, EXECUTE and DEBUG commands. LOAD performs a straightforward load process (along with any necessary translation of source files). EXECUTE is equivalent to loading with the /E switch (on termination of loading, transfer control to user's starting address). DEBUG is equivalent to loading with the /F switch (load DDT from device SYS:, turn on /S switch, and transfer control to DDT on termination of loading).

Loader switches can be passed to the Loader by prefixing them with a % symbol.

CHAPTER 1
INTRODUCTION

DDT-10 (for Dynamic Debugging Technique)* is used for on-line checkout and testing of MACRO-10 and FORTRAN programs and on-line program composition in all PDP-10 software systems. After the user's source program has been assembled or compiled, the user's binary object program (with its symbol table) may be loaded along with DDT. DDT occupies about 2K of core.

By typing commands to DDT, the user may set breakpoints where DDT will suspend execution of his program and await further commands. This allows the user to check out his program section by section. Either before starting execution or during breakpoint stops, the user may examine and modify the contents of any location. Insertions and deletions may be done in symbolic source language or in various numeric and text modes at the user's option. DDT also performs searches, gives conditional dumps, and calls user-coded debugging subroutines at breakpoints.

Symbolic on-line debugging with DDT provides a means for rapid checkout of new programs. If a bug is detected, the programmer makes changes quickly and easily and may then immediately execute the corrected section of his program.

1.1 LOADING PROCEDURE

The user loads the program to be debugged and DDT with the Linking Loader. (The /D switch commands the Loader to load DDT.) To transfer control to DDT, the user types the Monitor command,

```
DDT
```

After DDT responds by skipping two lines, the user may begin typing commands to DDT.

1.2 LEARNING TO USE DDT

This manual is designed to make DDT easy to use. A survey was made of several programmers who use DDT frequently, and it was learned that most debugging is done with a limited set of commands. These basic commands are described in the next chapter. When learning DDT, it is recommended that the reader concentrate on learning to use the commands in Chapter 2. If more detailed information is required, skip ahead to later chapters.

*Historical footnote: DDT was developed at MIT for the PDP-1 computer in 1961. At that time DDT stood for "DEC Debugging Tape." Since then, the idea of an on-line debugging program has propagated throughout the computer industry. DDT programs are now available for all DEC computers. Since media other than tape are now frequently used, the more descriptive name "Dynamic Debugging Technique" has been adopted, retaining the DDT acronym. Confusion between DDT-10 and another well known pesticide, dichloro-diphenyl-trichloroethane (C_2H_4Cl_2), should be minimized since each attacks a different, and apparently mutually exclusive, class of bugs.

1-1
After reading Chapter 2, practice debugging, using the basic commands. This may be all that will ever be needed. Read the following chapters which describe the entire command set in detail; this should be read when the basic commands are understood.

After learning the system, the Summary of Commands, listed by function in Appendix A, will be useful for quickly finding any DDT command. This summary, along with the chapter on Basic Commands, is also available in the PDP-10 Systems User's Guide (DEC-10-NGCA-D).
CHAPTER 2
BASIC DDT COMMANDS

The DDT commands most frequently used by programmers are described in this chapter. Many programs are debugged successfully using only these basic commands.

This chapter introduces the main features of DDT to the uninitiated user. Later chapters describe in detail these basic commands, less frequently used commands and other more complex options.

2.1 EXAMINING STORAGE WORDS

By using DDT, a programmer may examine the contents of any storage word by typing the address of the desired word followed immediately by a slash (/). For example, to type out the contents of a location whose symbolic address is CAT, the user types:

```
CAT/  
```

DDT now types out the contents (preceded and followed by tabs) on the same line. The word labeled CAT is now considered to be opened, and DDT has set its location pointer to point to this address.

2.2 TYPE-OUT MODES

The preceding example showed DDT typing out the contents of location CAT as a symbolic instruction with its address field also relative to a symbol. This is the type-out mode in which DDT is initialized. It is also initialized to type all numbers in the octal radix. The user may ask DDT to re-type the preceding quantity as a number in the current radix by typing an equal sign (=). For example:

```
CAT/  MOVEK AC,DOG+21 = 202400,6736  
```

DDT has numerous commands which reset the type-out mode permanently, temporarily, or for only one typeout. The modes that can be selected include numeric constants, floating point numbers, ASCII and SIXBIT text modes, and half-word format. Absolute or relative addressing and different radices may similarly be selected. For example, to change the current type-out mode to ASCII text, the user types the command:

```
```

1 In this manual information typed out by DDT is underlined to distinguish DDT output from user-typed input.

2 The two commas indicate that 202400 is in the left half of CAT, and 6736 is in the right half.

3 The Teletype keys ALTMODE (ALT), PREFIX (PREFIX), or ESCAPE (ESC) are all equivalent and echo as $. 

2-1
or, to change the current type-out mode to half-word format, he types

$SH

or, to select decimal numbers in his typeouts, he types

$10H

Using these commands (and others described in Chapter 3), a programmer may examine any location in the mode most appropriate to the information stored there. The semicolon (;) commands

DDT to retype the preceding quantity in the current mode. Combining this command with a mode change gives results such as the following:

```
CAT/  MOVEK ACxDOG+21  $10K  MOVEK ACxDOG+17
or
CAT/  MOVEK ACxDOG+21  $H;  202400,DOG+21
or
TEXT/  ANDM 1,342212(10)  ST;  ABCDE
```

2.3 MODIFYING STORAGE WORDS

Once a word has been opened, its contents may be changed by typing the desired new contents immediately following the typeout produced by DDT. A carriage return will command DDT to make the indicated modification and close the word. For example,

```
CAT/  MOVEK ACxDOG+21  KMVNK AC2xDOG+21)
```

The carriage return simply closes the previously examined register without opening another.

The line feed (1) may also be used to close a word after examining (and optionally modifying) it. The line feed also commands DDT (1) to echo a carriage return, (2) close the current word (making a modification if one was typed), (3) add one to DDT's location pointer, and (4) type out the new pointer value and the contents of that address. Thus, if a line feed had been used in the previous example, the result would be:

```
CAT/  MOVEK ACxDOG+21  KMVNK AC2xDOG+21)
CAT+1/  AORJN XR6, LOOP5
```

Location CAT+1 is now open and may be modified if desired.

The vertical arrow (1) is similar to the line feed command except that the location counter is decremented by one. Therefore, if the user continued the previous example by typing 1 the result would be

```
CAT+1/  AORJN XR6, LOOPS+1
CAT/  KMVNK AC2xDOG+21
```

---

1 The carriage return command has the additional property of causing temporary type-out modes to revert to permanent mode.
Location CAT is thus displayed and shows the result of the modification made in the previous example.

The tab (→) and backslash (\) both close the current register and open the address last typed (whether typed by DDT or the user). However, tab sets DDT's location pointer (. ) to this new address while backslash leaves it unaltered. A more complex example may clarify the usefulness of these commands.

```
CAT+1/ AOBJR6 XR6,LOOPS ←
LOOPS/ CAMGE AC2, TABL(XR6) CAMG
         AC2, TABL+1(XR6) SETI 0=401000 , 0 ↓
LOOPS+1/ JUMPL AC3,FAULT JUMPL AC2,FAULT ←
FAULT/ JRST 4,FAULT
```

2.4 TYPE-IN MODES

The examples in the preceding section showed modifications made as symbolic instructions in a form identical to MACRO-10 machine language. It is also possible to enter various numbers and forms of text.

Octal values may be typed in as octal integers with no decimal point. Numeric strings with numbers following the decimal point imply decimal floating-point numbers. The E-notation may also be used on floating-point numbers. Some examples are:

- Octal: 1234 7777777777 -6 0
- Decimal integers: 6789 9999999. -25. 0.
- Floating-point numbers: 78.1 0.249876E-10 -4.00E+20 0.0
- Incorrect formats: 76E+2 76.E+2 instead write 76.0E+2

To enter ASCII text (up to five characters left justified in a word), type a double quote (" ) followed by any printing character to serve as a delimiter, then type the one to five ASCII characters and repeat the delimiter. For example:

```
"ABCD\E" (\ is the delimiter)
"ABCD\A (\ is the delimiter)
```

Note that the mode of a quantity typed in is determined by the user's input format and is unaffected by any type-out mode settings.

2.5 SYMBOLS

The user's symbol tables are loaded by the Linking Loader when it loads programs and DDT. However, initially DDT is set to treat only global symbols (created by INTERNAL and ENTRY pseudo-ops in MACRO-10) as being defined. This means that only global symbols will be used for relative
address typeouts and, likewise, only these globals can be referenced when typing in symbolic modifications. In order to make the local symbols within a particular program available to DDT, the user types the program name (this comes from the MACRO-10 TITLE statement or the FORTRAN IV SUBROUTINE or FUNCTION statement) followed by ALTMODE and a colon ($:). For example, the command

```
ARCTAN$:
```

will unlock the local symbols in the program named ARCTAN. This provision in DDT permits the user to debug several related subroutines simultaneously and reference the local symbol table of each independently without fear of multiply-defined local symbols. If the user’s program is not titled, the command MAIN$: will unlock the local symbol table.

The user may also insert symbols into the symbol table. To insert a symbol with a particular value, type the value, followed by a left angle bracket (<), the symbol, and a colon (:). Some examples are

```
707<CONS: 27<X: 12.1E+2<NUMS: ADK+12<ADRX:
```

To assign a symbol with a value equal to DDT’s location pointer, simply type the symbol followed by a colon. For example,

```
XFER+4/ JRST & TABL(3) BRNCH:
```

will cause BRNCH to be defined with the value XFER+4.

2.6 EXPRESSIONS

DDT permits the user to combine symbols and numeric quantities into expressions by using the following characters to indicate arithmetic operators.

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>The plus sign indicates 2’s complement addition</td>
</tr>
<tr>
<td>-</td>
<td>The minus sign indicates 2’s complement subtraction</td>
</tr>
<tr>
<td>*</td>
<td>The asterisk indicates integer multiplication</td>
</tr>
<tr>
<td>'</td>
<td>The single quote or apostrophe indicates integer division (remainder discarded) -- slash cannot be used to indicate division since it has another use in DDT.</td>
</tr>
</tbody>
</table>

As usual in arithmetic expressions, the evaluation proceeds from left to right with multiplication and division performed before addition and subtraction.

2.7 BREAKPOINTS

The breakpoint facility in DDT provides a means of suspending program operation at any desired point to examine partial results and thus debug a program section by section. The simpler facts about breakpoints are presented next; the use and control of conditional breakpoints is deferred to Paragraph 4.2.
2.7.1 Setting Breakpoints

The programmer can automatically stop his program at strategic points by setting as many as eight breakpoints. Breakpoints may be set before the debugging run is started, or during another breakpoint stop. To set a breakpoint, the programmer types the symbolic or absolute address of the word at the location point in which he wants the program to stop, followed by $B$. For example, to stop when location 6004 is reached, he types,

`6004B`

Breakpoint numbers are normally assigned by DDT in sequence from 1 to 8. The user may instead assign breakpoint numbers himself when he sets a breakpoint by typing,

`SNB`

where n is the breakpoint number ($1 \leq n \leq 8$), for example,

`CAT+354B  DOG+157B  600456B`

When the programmer sets up a breakpoint he may request that the contents of a specified word be typed out when the breakpoint is reached. To do this, the address of the word to be examined is inserted, followed by two commas, before the breakpoint address. Some examples are

`DOG+CAT+63B  AC1+LOOP+25B  X+600456B`

2.7.2 Breakpoint Restrictions

The locations where breakpoints are set may not

a. be modified by the program
b. be used as data or literals
c. be used as part of an indirect addressing chain
d. contain the user mode Monitor command, INIT.

2.7.3 Breakpoint Type-Outs

When the breakpoint location is reached, DDT suspends program execution without executing the instruction at the breakpoint location. DDT then types the breakpoint number and the Program Counter value at the time the breakpoint is reached (this value will differ from the typed-in breakpoint address if the breakpoint is executed by an XCT instruction elsewhere in the program). The format of this typeout is as shown in the following examples:

`$4B >> CAT+3  17K >> DOG+1  5Nh >> 604A`

If the user requested that a specified address be examined at that breakpoint, it will be opened; for example,

`$3B >> CAT  DOG/ S0JGE 3,0CAT+6`
2.7.4 Removing and Reassigning Breakpoints

The user may remove a breakpoint by typing,

\[ \text{\texttt{\$SNB}} \]

where \( n \) is the number of the breakpoint to be removed. For example,

\[ \text{\texttt{\$S2B}} \]

removes the second breakpoint. All assigned breakpoints are removed by typing

\[ \text{\texttt{\$B}} \]

The user may reassign a breakpoint without formally removing it. Thus, if he has set breakpoint No. 2 at location ADR (via the command ADR\$2B) he may reassign No. 2 to LOC+6 by typing LOC+6\$2B.

2.7.5 Proceeding From a Breakpoint

Program execution may be resumed (in sequence) following a breakpoint stop by typing the proceed command, \( \text{\texttt{\$P}} \).

If the user does not wish to stop until the \( n \)th time that this breakpoint is encountered he types,

\[ \text{\texttt{\$NP}} \]

Then this breakpoint will be passed \( n-1 \) times before a break occurs.

2.8 STARTING THE PROGRAM

The program is started by typing

\[ \text{\texttt{\$G}} \]

This starts the program at the previously specified starting address in location JOBSA. (Typically this is the address from the MACRO-10 END statement.) The programmer may start at any other location by typing that address followed by \( \text{\texttt{\$G}} \). For example,

\[ \text{\texttt{4000\$G}} \]

starts the program at the instruction stored at location 4000. BEGIN\$G starts the program at the symbolic location BEGIN.

The start command may also be used to restart from a breakpoint stop when it is not desired to continue in sequence from the point where program execution was suspended.

2.9 DELETING TYPING ERRORS

Any partially typed command may be deleted by pressing the RUB OUT key. This causes DDT to ignore any preceding (unexecuted) partial command, and DDT types XXX. The correct command may then be retyped.
2.10 ERROR MESSAGES

If the user types an undefined symbol which cannot be interpreted by DDT, U is typed back.
If an illegal DDT command is typed, or a location outside the user's assigned memory area is referenced
? is typed back.

2.11 SUMMARY

As was said in the beginning, these basic commands are sufficient for debugging many
programs. Complete descriptions of all DDT commands are explained in the following chapters.
CHAPTER 3
DDT COMMANDS

When DDT is initialized, it is set to type out in the symbolic instruction format with relative addresses, and to type out numbers in octal radix.

3.1 EXAMINING THE CONTENTS OF A PROGRAM STORAGE WORD

To type out the contents of a storage word, the programmer types the address, followed immediately by a slash (/). For example, to examine the contents of a word whose symbolic address is ADR, the user types,

ADR/

DDT types out the contents on the same line. In this manual, information typed out by DDT is underlined.

ADR/ MOVE A, CC1

The word labeled ADR is now considered to be opened, and DDT continues to point to this address. The point, or period, character (.) represents DDT’s location pointer, and may be used to type out its contents, as in the following command.

.* MOVE A, CC1

Since we did not change the contents, they are the same, but we used the location pointer to re-examine the currently opened word. Similarly, the programmer may use the period (.) as an arithmetic expression component, such as

*+5/ S0JGE 2*ADRX+3

DDT’s location pointer is set to a new value by the / command when preceded by an address. For example,

201/.

sets the location pointer to 201. If the user types / without typing an address, the contents of the location addressed in the last typeout are typed.

667/ MOVE 1,6 / 0

.* MOVE 1,6

Location 667 contains the instruction MOVE 1,6. The second slash displays the contents of Accumulator 6, which is zero. This does not change the location pointer, which is still pointing to location 667.

ADR/ MOVE A, CC1 / ADD 2*SUX+7

It should also be noted that the spaces which occur after DDT complete the typing of the contents of ADR are automatically produced by DDT, not the user.
The left square bracket ([])\(^1\) has the same effect as the slash, (the address immediately preceding the [ will be opened). However, [ forces the typeout to be in numbers of the current radix.

ADR [ 9. ] (DECIMAL)

The right bracket (])\(^*\) has the same effect as the slash except that it forces the typeout to be in symbolic instructions.

ADR+23 ] MOVE 15,LIST+2.

The exclamation point (!) works like the slash except that it suppresses type out of contents of locations until either /, [, or ] is typed by the user. The LINE FEED (!) commands DDT to type out the contents of ADR+1.

ADR! MOVE AC,555 ] (1)
ADR+1! ] (2)
ADR/ MOVE AC,555 ] (3)

Thus, in step (1) of the example the contents of ADR are not typed out, but the address is opened to modification and MOVE AC,555 has been typed in by the user.

Step (2) of the example shows that the location pointer has been incremented by one and the contents of ADR+1 are not typed out. This is because the exclamation point is still in effect and will continue to take effect until /, [, or ] is typed in by the user. In this case, the slash terminates the effect of the exclamation point.

Step (3) shows that the modification (MOVE AC,555) of ADR typed in Step (1) has been accomplished.

3.2 Changing the Contents of a Word

After a word is opened, its contents can be changed by typing the new contents following the type out by DDT, followed by a carriage return. For example,

ADR/ MOVE A,CC1 MOVE A,CC2 ]

The carriage return closes the open word, but does not move the location pointer. A LINE FEED (!) command could also be used to make this modification. A LINE FEED causes a carriage return, adds

---

\(^1\) On Teletype Models 33 and 35 the left square bracket ([]) is produced by holding the SHIFT key down and striking the K key. The right square bracket (]), is produced by holding the SHIFT key down and striking the M key.

3-2
one to DDT's location counter (moves the pointer), types out the resulting address and the contents of the new address. Thus, if we conclude our last example with a LINE FEED

ADR/ MOVE A×CC1 MOVE A×CC2
ADR+1/ ADD 3×CC3

ADR+1 is now open, and may be modified by the user.

The vertical arrow (↑) works similarly, except that one is subtracted from the location pointer. The open word is closed (modified if a change is given) and the new address and contents are typed out.

ADR+1/ ADD 3×CC3↑
ADR/ MOVE A×CC2

Since the vertical arrow subtracts one from the pointer, the resulting address is ADR, and the contents now show the change made in the previous example.

3.3 INSERTING A CHANGE, AND EXAMINING THE CONTENTS OF THE LAST TYPED ADDRESS

The horizontal tab (→) causes a carriage-return line feed, then sets the location pointer to the last address typed (the new address if a modification was made) of the instruction in the register just closed. Then DDT types this new address, followed by a slash and the contents of that location, as shown below.

ADR5/ JRST ADR↓ JRST ADR →
ADR/ MOVE B×CC2 →
CC2/ 666

The backslash (\) opens the word at the last address typed and types out the contents. However, backslash does not change the location pointer. The backslash closes the previously opened word and causes it to be modified if a new quantity has been typed in.

ADR/ MOVE A×CC2 JRST X \ MOVE AC,3

The use of the backslash accomplishes two things. First it changes ADR by replacing its contents with JRST X. Second, the backslash causes DDT to type out the contents of X, namely, MOVE AC,3. The location pointer continues to point to ADR, but now location X is open and may be modified if desired.

---

1↑ is produced by SHIFT-N on Teletype Models 33 and 35. The backspace key may be used instead of ↑ on Teletype Model 37.

2\ is produced by SHIFT-L on Teletype Models 33 and 35.
If the line-feed control character and the vertical arrow were used in conjunction with the backslash, the results would be as follows.

<table>
<thead>
<tr>
<th>Command Character</th>

</tbody>
</table>

A ? typed by DDT when examining a location indicates that the address of the location is outside the user's assigned memory area. A ? typed when depositing indicates that the location cannot be written in, because it is either outside the assigned memory area or inside DDT or inside a write-protected memory segment.

1. If a user-typed quantity preceded.
2. If I has not suppressed typeout.
3.4 STARTING THE PROGRAM

The program is started by typing

\( SG \)

This starts the program with the instruction beginning at the user’s previously specified starting address taken from location JOBSA. The programmer may start at any other instruction by typing the address of that instruction followed by \( SG \). For example,

\[ 4000SG\text{ OR}\text{ ADR+5SG} \]

starts the program at the instruction stored at location 4000 or, in the second part, at the symbolic address ADR+5. The start command may also be used to restart from breakpoints when the user does not wish to proceed to the next instruction.

3.5 ONE-TIME TYPEOUTS

These commands cause a single typeout of the opened word in the mode indicated.

3.5.1 Type Out Numeric

Although DDT is initialized to type out in symbolic mode, it is often useful to change to numeric typeout. When the programmer types the equal sign (=), the last expression typed is retyped by DDT in the current radix (initially octal). This is useful when a symbolic typeout is meaningless. Since this usually indicates that numeric data is stored in that word, the user can verify this by typing - and checking the value.

3.5.2 Type Out Symbolic

If a typeout is numeric, and the user wants to examine it in symbolic mode, he types the left arrow (\( \leftarrow \)). The last typed quantity is retyped as a symbolic instruction. The address mode is determined by \( SA \) or \( SR \).

3.5.3 Type Out in Current Mode

To retype a typeout in the current mode, the user types a semicolon (;). This may be used, for example, if the user has changed the typeout mode. For example,

\[ \text{TEXT/ ANDM } 1 \times 342212 (10) \text{ STS ABCDE} \]

3.6 SYMBOLS

Before DDT commands can be used to reference local symbols in the program Symbol Table, the user must type the program name as specified in the MACRO-10 TITLE statement, or the FORTRAN IV
SUBROUTINE or FUNCTION statement, followed by a dollar sign and a colon. For example,

\begin{verbatim}
MAIN5:
\end{verbatim}

makes the local symbols in the program called MAIN available. Since the user can debug several
related subroutines simultaneously, reference to several independent symbol tables is permitted, each
of which may use the same local symbols with different values. Global symbols, such as those specified
in MACRO-10 INTERNAL statements, may always be referenced.

The user may insert (or redefine) a symbol in the symbol table by typing the symbol, followed
by a colon. The symbol will have a value equal to the address of the location pointer (\_).

\begin{verbatim}
X/ ADD1 #N TAG:
\end{verbatim}

causes TAG to be defined with the same value as X. All user defined symbols are global.

The user may also directly assign a value to a symbol by typing the value, a left angle
bracket (<) and the symbol, terminated by a colon. This is the equivalent of a MACRO-10 direct
assignment statement. Some examples are,

\begin{verbatim}
707 <CONS: 12*1E+2<NUMB:
27<X: 181<MIL:
\end{verbatim}

3.7 \section{Typing In}

To change or modify the contents of a word, the user may type symbolic instructions, numbers,
and text characters. Type-ins are interpreted by DDT in context. That is, DDT tests the data typed in
to determine whether it is to be interpreted as an instruction, a number (octal or decimal), or text.

Typeout mode settings, such as \$S, \$C, and \$nR, do not affect typed input.

The user may type the following:

\begin{itemize}
  \item[a.] Symbolic Instructions
  \item[b.] Numbers
    \begin{enumerate}
      \item Octal integers
      \item Fixed-point decimal integers
      \item Floating-point decimal mixed numbers
    \end{enumerate}
  \item[c.] Text
    \begin{enumerate}
      \item Up to five PDP-10 ASCII characters, left justified in a word
      \item Up to six SIXBIT characters, left justified in a word
      \item A single PDP-10 ASCII character, right justified in a word
      \item A single SIXBIT character, right justified in a word
    \end{enumerate}
  \item[d.] Symbols
    Anything that is not a number or text is interpreted by DDT as a symbol.
\end{itemize}
3.7.1 Typing In Symbolic Instructions

In general, a new symbolic instruction is written for insertion by DDT, in the same way the
instruction is written as a MACRO-10 source program statement. For example,
\[ \text{X/ } \emptyset \text{ ADD AC1 DATE} \]
where a space terminates the operation field, and a comma terminates the accumulator field. For
example: (1) In DDT, the operation code determines the interpretation of the accumulator field. If
an I/O instruction is used, DDT inserts the I/O device number in the correct place, and (2) indirect
and indexed addresses are written, as in MACRO-10 statements, where @ precedes the address to set
the indirect bit, and the index register specified follows in parentheses.
\[ \text{X/R ADD } \emptyset \text{ } @\text{ENUM (17)} \]
To type in two 18-bit halfwords, the left and right expressions are separated by two commas.
For example,
\[ \text{X/ } \emptyset \text{ A,,B} \]
This is similar to the MACRO-10 statement
\[ \text{XWD A,B} \]

3.7.2 Typing In Numbers

A typed-in number is interpreted by DDT as octal if it does not contain a decimal point.
The following examples are octal type-ins:
\[ 1234 \quad -10101 \]
\[ 772 \quad 777777777777 \]
Fixed-point decimal integers must contain a decimal point with no digits following.
\[ 1234. \quad -99. \quad 877. \]
Floating-point numbers may be written in two formats. With a decimal point and a digit following the
decimal point:
\[ 101.1 \quad 1234.5 \quad 999.0 \quad -2.71828 \]
Or as in MACRO-10, with E indicating exponentiation:
\[ 12.0E+2 \quad 77.0E+5 \quad 12.34E2 \quad 31.4159E-1 \]

3.7.3 Typing In Text Characters

To type in up to five PDP-10 ASCII characters, left justified in an opened word, the user
types a quotation mark, followed by any printing delimiting character, then the text characters, and
terminated by the delimiting character. The following examples are legal:
\[ "\text{TEXT/} \quad "\text{ABCD\text{\&}} \quad \text{FA} \quad \text{In these cases, / and A are} \]
the delimiting characters
Lower case letters are converted to upper case. Characters outside the SIXBIT set are illegal, and DDT types a ?

To type in up to six SIXBIT characters, left justified in an opened word, the user types "$", followed by any delimiting character, then the text characters, and terminated by repeating the delimiting character. The two examples below are SIXBIT type ins.

\$"DIVIDE/ \$"XXXXXXXE

To type in a single PDP-10 ASCII character, right justified in an opened word, the user types a quotation mark, followed by a single ASCII text character, then by an ALT MODE.

'0$ "/ "?$

To type in a single SIXBIT character, right justified in an opened word, the user types an ALT MODE, followed by a quotation mark, a single SIXBIT text character and terminated by an ALT MODE.

\$"GS \$"MS \$"SS

3.7.4 Arithmetic Expressions

Numbers and symbols may be combined into expressions using the following characters to indicate arithmetic operations.

+ The plus sign means 2's complement addition.
- The minus sign means 2's complement subtraction.
* The asterisk means integer multiplication.
' The single quote means integer division with any remainder discarded. (The Slash has another function.)

Symbols and numbers are combined by +, -, *, ' to form expressions. Examples:

6+2
S*2.51+B
2*3+1

3.8 DELETE

Any partially typed command may be deleted by pressing the RUB OUT key. This causes DDT to ignore any preceding (unexecuted) partial command and DDT types XXX. The correct command may then be retyped.

3.9 ERROR MESSAGES

If the user types an undefined symbol which cannot be interpreted by DDT, U is typed back. If an illegal DDT command is typed, ? is typed back. Examining or depositing into a location outside
the user's assigned memory area causes DDT to type a ? Depositing in a write-protected high memory segment also results in a ? timeout.

3.10 UPPER AND LOWER CASE (TELETYPEx MODEL 37)

DDT will accept alphabetic input in either upper or lower case. Lower case letters are internally converted to upper case, except when inputting text where they are taken literally as explained in Section 3.7.3.

DDT output is in upper case, except for text which is taken literally.
CHAPTER 4
MORE DDT-10 COMMANDS

This chapter describes other type-out modes, conditional breakpoints, searches and additional features. Commands are available to reset the initial settings so that numeric data can be typed out in a radix chosen by the user, in floating-point format, in RADIX30 format, as halfwords (two addresses) and as bytes of any size. The contents of a storage word may also be typed out as 7-bit PDP-10 ASCII text, or SIXBIT text characters. (See MACRO-10 Manual, Appendix 5.)

Searches can be made in any part of the program for any word, not-word (inequality), or effective address. The user specifies the instruction or data to be searched for and the limits of the search.

Breakpoints can be set conditionally, so that a program stop occurs if the condition is satisfied. In addition, a counter can be set up allowing the user to specify the number of times a breakpoint is passed before a program stop occurs.

4.1 CHANGING THE OUTPUT RADIX

Any radix ($\geq 2$) may be set by typing $\$nR$, where $n$ is the radix for the next typeout only, and $n$ is interpreted by DDT as a decimal value. The radix is permanently changed when the double dollar sign is used in the command $\$\$nR$. To change the type-out radix permanently to decimal, the user types,

\[\$\$10R\]

When the output radix is decimal, DDT follows all numbers with a point.

4.2 TYPE OUT MODES

When DDT-10 is loaded, the type-out modes are initialized to produce symbolic instructions with relative addresses. For numeric typeouts, the radix is initially set to octal.

These modes may be changed by the user. The duration, or lasting effect of a type-out mode change is also set by the user. Prevailing modes, which are semipermanent, are preceded by a single dollar sign. In addition, some mode changes effect only one typeout, such as the equal sign, which causes DDT to retype the last typed quantity in numeric mode.

In general, prevailing modes are changed by replacing them with another prevailing mode or by reinitializing the system. Temporary modes remain in effect until the user types a carriage return ($\text{\textbackslash r}$), or re-enters DDT. One-time modes apply only to a single typeout.
4.2.1 Primary Type-out Modes

$S$ (OR $SS$) Type out symbolic instructions. The address part interpretation is set by $SR$ or $SA$.

\[ \text{$S$ ADR/ ADD A1, TABLE+3} \]

$SA$ (OR $SA$) Type out the address parts of symbolic instructions, and both addresses when the mode is halfword, as absolute numbers in the current radix.

\[ \text{$SA$ ADR/ ADD 4000} \]

$SR$ (OR $SR$) Type out addresses as relative addresses.

$SC$ (OR $SC$) Type out constants, i.e., as numbers in the current radix.

\[ \text{$SC$ ABLE/ } 254111110750 \]

$SF$ (OR $SF$) If the output radix octal and the left half is not 0, the word will be divided into halves separated by commas. Type out the contents of storage words as floating-point numbers.

\[ \text{$SF$ X/ #0.17516230E+45} \]

The number sign (#) indicates the number is unnormalized.

$ST$ (OR $ST$) Type out as 7-bit ASCII text characters. Left-justified characters are assumed unless the leftmost character is null. If the leftmost character is null, then right-justified characters are assumed.

\[ \text{$ST$ REX/ ABCDE} \]

$S6T$ (OR $S6T$) Type out as SIXBIT text characters.

\[ \text{$S6T$ REX/ ABCDEF} \]

$SST$ (OR $SST$) Type out symbols in radix 50 mode. (See MACRO-10 Manual, Appendix 6.)

\[ \text{$SST$ 13774/ } 4 \text{CKEF = 40003, 261550} \]

$SH$ (OR $SH$) This command causes the typeout to be in halfwords, the left half separated from the right half by double commas. The address mode interpretation is determined by $SR$ or $SA$.

\[ \text{$SA$ SH Z/ 4503, 4502} \]

\[ \text{$SR$ SH Z/ TABL+14, TABL+13} \]

$SNO$ (OR $SNO$) Type out in $n$-bit bytes, where $n$ is decimal. (Use the letter O, not zero).

\[ \text{$SNO$ BYTS/ 22, 23, 13, 73, 51, 46} \]

As in all DDT typeouts, leading zeros are suppressed.
4.3 BREAKPOINTS

4.3.1 Setting Breakpoints

The programmer can automatically stop his program at strategic points by setting up to eight breakpoints. Breakpoints may be set before the debugging run is started, or during another breakpoint stop. To set a breakpoint, the programmer types the symbolic or absolute address of the word at the location which he wants the program to stop, followed by $B. For example, to stop when location 4002 is reached, he types:

4002$B

If all eight breakpoints are in use, DDT will type a question mark. The user may assign breakpoint numbers when he sets a breakpoint by typing ADR $nB, where n is the breakpoint number (1<n<8). For example,

SYM$3B ADR$7B

If n is not entered DDT will assign 1 through 8 in sequence. In the previous example, when ADR is reached, DDT types,

$7B >> ADR

indicating that the break has occurred at location ADR, and breakpoint No. 7 was encountered. The break always occurs before the instruction at the breakpoint address is executed.

If the instruction at the breakpoint location is executed by an XCT instruction, the typeout will show the address of the XCT instruction, not the location of the breakpoint. The program stops at each breakpoint address, and the programmer can then type other commands to examine and debug his program.

When the programmer sets a breakpoint, he may request that the contents of a word be typed out when a breakpoint is reached. To do this, the address of the word to be examined is inserted, followed by two commas, before the breakpoint address.

X,,4002$2B

When address 4002 is reached, DDT types out,

$2B,,4002 X/ ADD AC,Y+2

where ADD AC,Y+2 is the contents of X. Location X is left open at this point. Location 0 may not be typed out in this way because a zero argument implies no typeout.

4.3.2 Removing Breakpoints

The user may remove a breakpoint by typing,

$S NB
where \( n \) is the number of the breakpoint to be removed. Therefore,
\[
\$2B
\]
removes the second breakpoint. All assigned breakpoints are removed by typing
\[
\$B
\]
The user may reassign a breakpoint. If he has set breakpoint No. 2 at location ADR (ADR\$2B), he may reassign No. 2 to ADR+1 by typing ADR+1\$2B.

4.3.3 Restrictions for Breakpoints

Breakpoints may not be set on instructions that are
a. Modified by the program
b. Used as data or literals
c. Used as part of an indirect addressing chain
d. The user mode Monitor command, INIT

A breakpoint at any other Monitor command will operate correctly, except that if the Monitor command is in error, the Monitor will type out an error and the Program Counter, but the Program Counter will be internal to DDT and meaningless to the user.

4.3.4 Restarting After a Breakpoint Stop

To resume the program after stopping at a breakpoint, the user types the proceed command,
\[
\$P
\]
The program is restarted by executing the instruction at the location where the break occurred. If the user types n\$P, this breakpoint will be passed \( n-1 \) times before a break can occur; the break will occur the \( n \)th time. If \( n \) is not specified, it is assumed to be one. If the user proceeds by typing \$SP (or n\$SP), the program will proceed automatically when the program breaks again. If DDT encounters an XCT loop or the Monitor command INIT when proceeding, a question mark will be typed.

Alternatively, the user may restart at any location by typing the start command,
\[
\text{ADR}\$G
\]
where ADR is any program address, or \$G, which restarts at the previously specified starting address in location JOBSA.

4.3.5 Automatic Restarts from Breakpoints

If the user requests DDT to type out the contents of a word and then continue program execution without stopping, he types two ALTMODES when specifying the breakpoint address.
\[
\text{AC, ADR}$S$B
\]
When ADR is encountered, the contents of AC are typed out and program execution continues. To get out of the automatic proceed mode, remove the breakpoint or reassign it with a single $; it may be necessary to use $C$ and DDT to get back to DDT to do this. In executive mode, hit any teletype key during the timeout.

4.3.6 Checking Breakpoint Status

The user may determine the status of a breakpoint by examining locations $nB$, $nB+1$, and $nB+2$.

$nB$ contains the address of the breakpoint in the right half; the address of the location to be examined in the left half. If both halves equal zero, the breakpoint is not in use.

$nB+1$ contains the conditional breakpoint instruction. (See Paragraph 4.3.7.)

$nB+2$ contains the proceed count.

4.3.7 Conditional Breakpoints

Breakpoints may be set up conditionally in two ways. The user may provide his own instruction or subroutine to determine whether or not to stop, or he may set a proceed counter which must be equal to or less than zero in order for a break to occur.

When a breakpoint location is reached, DDT enters its breakpoint analysis routine consisting of five instructions.

```
SKIP  $\text{E}$  $nB+1$  ; Is the conditional break instruction 0?
XCT   $\text{E}$  $nB+1$  ; No, execute conditional break instruction
SOSG  $\text{E}$  $nB+2$  ; Decrement and test the proceed counter
JRST  break routine
JRST  proceed routine
```

If the contents of $nB+1$ are zero (indicating that there is no conditional instruction), the proceed counter at $nB+2$ is decremented and tested. If it is less than or equal to zero, a break occurs; if it is greater than zero the execution of the user's program proceeds with the instruction where the break occurred.

If the conditional break instruction is not zero, it is executed. If the instruction (or the closed subroutine) does not cause a program counter skip, the proceed counter is decremented and tested as above. If a program counter skip does occur, a break occurs. If the conditional instruction is a call to a closed subroutine which returns skipping over two instructions, execution of the user's program proceeds.
If the user wishes a break to occur based only on the conditional instruction, he should set the proceed counter to a large number so that the proceed counter will never reach zero.

4.3.7.1 **Using the Proceed Counter** - If the user wishes to proceed past a breakpoint a specified number of times, and then stop, he inserts the number of passes in $nB+2$, which contains the proceed count.

The proceed counter may be set in two ways. The first way is by direct insertion. For example,

\[
\text{SNB+2/ 0 20}
\]

sets the counter to 20. The second method is as follows. After stopping at a breakpoint, the proceed count may be set (or reset) by typing the count before the proceed command:

\[
\text{20SP}
\]

4.3.7.2 **Using the Conditional Break Instruction** - The user inserts a conditional instruction, or a call to a closed subroutine at $nB+1$. For example,

\[
\text{3B+1/ 0 CAIE AC+15)}
\]

or

\[
\text{4B+1/ 0 JSA 16, TEST)}
\]

When the breakpoint is reached, this instruction or subroutine is executed. If the instruction does not skip or the subroutine returns to the next sequential location, the proceed counter is decremented and tested, as explained in Paragraph 4.2.7. If the instruction skips or the subroutine returns skipping over one instruction, the program breaks. If the subroutine causes a double skip return, the program proceeds with the instruction at the breakpoint address.

**Examples of Conditional Breakpoints**

If address 6700 is reached and DDT's No. 4 breakpoint registers are as follows:

\[
\begin{align*}
\text{4B/} & \quad \text{AC1, 6700} \\
\text{4B+1/} & \quad \text{CAIE AC+100} \\
\text{4B+2/} & \quad \text{200}
\end{align*}
\]

AC1 contains 100, and DDT types

\[
\text{4B+6700 AC1/ 100}
\]

Since AC1 contains 100, the compare instruction skips and the program breaks. If AC1 did not contain 100, $4B+2$ would be decremented by one and the user's program would continue running.
If the conditional break instruction transfers to a subroutine which, after the subroutine is executed, returns to the calling location +3, a break will never occur regardless of the proceed counter. Example: If the internal DDT breakpoint registers ($28$ and $28+1$) have the following contents, a break would not occur unless accumulator 3 contains 100.

```
$2B/ ADR
$2B+1/ JSR TEST
TEST/ 
TEST+1/ AOS TEST
TEST+2/ CAIE 3,100
TEST+3/ AOS TEST
TEST+4/ JRST @ TEST
```

(contains PC when JSR to subroutine TEST is made)

The subroutine TEST causes a double skip (the return is to the third instruction after the call) in DDT if accumulator 3 does not equal 100. A break will never occur at address ADR (regardless of the proceed counter) unless accumulator 3 contains 100.

4.3.8 Entering DDT from a Breakpoint

When a break occurs, the state of the user's program is saved, the JSR breakpoint instructions are removed, and the programmer's original instructions are restored to the breakpoint locations. DDT types out the number of the breakpoint and a symbol indicating the reason for the break, > for the conditional break instruction, >> for the proceed counter and the address in the user's program where the break occurred.

Example: If address ADR is reached in the user's program and DDT's breakpoint registers contain:

```
$2B/ ADR
$2B+1/ 0
$2B+2/ 0
```

(proceed counter contains zero)

DDT stops the program and types,

```
$2B>>ADR
```

4.4 SEARCHES

There are three types of searches: the word search, the not-word search, and the effective address search.

Searches can be done between limits. The format of the search command is,

```
a<b>c$ W Word search
```
where:

- **a** is the lower limit of the search; 0 is assumed if this argument and its delimiter are not present.
- **b** is the upper limit of the search. The lower numbered end of the symbol table is assumed if this argument and its delimiter are not present.
- **c** is the quantity searched for.

The effective address search (E) will find and type out all locations where the effective address, following all indirect and index-register chains to a maximum depth of 64 levels, equals the address being searched for.

Examples:

```
4517<5000>X$E
INPUT <5000>700$E
```

Examples of DDT output, when searching for X in the above example, are as follows.

```
4517/ SETZM X
4721/ MOVE 2,X
5000/ MOVE 3,x @ 4721 (indirectly addresses X through address 4721)
```

The word search (W) and the not-word search (N) compare each storage word with the word being searched for in those bit positions where the mask, located at $M$, has ones. The mask word contains all ones unless otherwise set by the user. If the comparison shows an equality, the word search types out the address and the contents of the register; if the comparison results in an equality, the word search will type out nothing. The not-word search types nothing if an equality is reached. It types the contents of the register when the comparison is an inequality.

Examples:

```
INP<INPT+10>NUM$W
INP<INPT+10>N$SN

$M/ This command types out the contents of the mask register, which is then open. The contents of the mask register are ordinarily all ones unless changed by the user.

N$SN/ Inserts n into the mask register.
```

4.5 **MISCELLANEOUS COMMANDS**

```
$Q/ $Q represents the value of the last quantity typed.
ADR/ 100 $Q+1)
ADR/ 101
INST$X/ Causes the instruction INST to be executed.
```

4-8
Example:

JRS T ADR$X would cause the user's program to be started at ADR.

There are a number of circumstances when the user will want to zero out certain memory location(s). The following command provides this capability:

FIRST<LAST $Z

This command will zero out the memory locations between the indicated FIRST address and LAST address inclusively. If the FIRST address is not present, the location 0 is assumed. If the LAST address is not present, the location before the low-numbered end of the symbol table is assumed. In no case will locations 20-137 nor any part of DDT or DDT's symbol table be zeroed.
CHAPTER 5
SYMBOLS AND DDT ASSEMBLY

A symbol is defined in DDT as a string of up to six letters and numbers including the special characters period (.), percent sign (%), and dollar sign ($). Characters after the sixth are ignored. A symbol must contain at least one letter. If a symbol contains numerals and only one letter, that letter must not be a B, D, or an E. These letters are reserved for binary-shifted and floating-point numbers.

Certain symbols can be referenced in one program from another. These symbols are called "global." Those which can only be referenced from within the same program are called "local" or "internal." Any symbol which has been defined as global by MACRO-10 (using the INTERNAL or ENTRY statements) will be considered as global by DDT-10 when it is referenced. FORTRAN subroutine entry points and COMMON block names are globals. All symbols which the user defines via DDT are considered to be global.

The user may want to reference a local symbol within a particular program. In order to do this he must first type the program name followed by $:. Thus, if a user wishes to use a symbol local to program MIN, he types the command,

MIN $:

This command unlocks the symbol table associated with MIN. The program name is that specified in the MACRO-10 TITLE statement. In FORTRAN, the program name is either MAIN, the name from the SUBROUTINE or FUNCTION statement, or DAT. for BLOCK DATA subprograms.

5.1 DEFINING SYMBOLS

There are two ways to assign a value to a symbol.

NUMERIC VALUE < SYMBOL:
This command puts SYMBOL into DDT-10's symbol table with a value equal to the specified NUMERIC VALUE. SYMBOL is any legal symbol defined or undefined.

Example:

305 < XVAR:
XVAR has now been defined to have the value 305.

TAG:
This command puts TAG into DDT-10's symbol table with a value equal to the address of the location pointer.

Example:

4001 ADD 2, 12012, X1
This puts the symbolic tag X into DDT-10's symbol
5.2 DELETING SYMBOLS

There are times when the user will want to restrict or eliminate the use of a certain few defined symbols. The following three ways give the user of DDT-10 these capabilities.

**SYMBOL $$K**

SYMBOL is killed (removed) in the user's symbol table. SYMBOL can no longer be used for input or output.

**Example**

$$K$$

This command removes the symbol X from the symbol table.

**SYMBOL $K**

This command prevents DDT from using this symbol for typeout; it can still be used for typein. For example, the user may have set the same numeric value to several different symbols. However, he does not wish certain symbol(s) to be typed out as addresses or accumulators.

**Example**

X/ MOVE J, SAV J$K = MOVE N, SAV N$K = MOVE AC, SAV

Since the user does not wish J to be typed out as an accumulator, he types in J$K, followed by a left arrow to type out the contents of X again and MOVE N, SAV is typed out. He then repeats the above process until the desired result, namely AC, is typed out. Any further symbolic typeouts with the same number in the accumulator field of the instruction will type out as AC.

**$D**

The last symbol typed out by DDT has $K performed on it. The value of the last quantity output is then retyped automatically. For example,

A/ MOVE AC, LOC $D MOVE AC, ABC+1

5.3 DDT ASSEMBLY

When improvising a program on-line to the PDP-10 on a Teletype, the user will want to use symbols in his instructions in making up the program. In this and in other situations, undefined symbols may be used by following the symbol with the number sign (#). The symbol will be remembered by DDT from then on. Until the symbol is specifically defined by the use of a colon, the value of the symbol is taken to be zero. Successive uses of the undefined symbol cause DDT to type out #. Appending # to all subsequent uses of the symbol enables the user to readily identify undefined (not yet defined by a colon) symbols.
Example:

MOVE 2, VALUE

VALUE is now remembered by DDT and may be used further without the user appending the $. If subsequent instructions are given involving VALUE, DDT appends a $ automatically to that symbol. Thus VALUE will always appear as VALUE followed by the $ (until VALUE is defined).

Example:

START! MOVE 2, VALUE $ (user types the $)
START+1! ADDI 2, 50 $
START+2! MOVEM 2 $ VALUE $
# $ $ (DDT types $)
START+3! JRST VALUE+$ $ (DDT types $ after the plus sign because only at that point does DDT realize the symbol VALUE is complete.)
START+4!

Undefined symbols can be used only in operations involving addition or subtraction. The undefined symbols may be used only in the address field.

Example:

MOVEI 2,3*UNDEF

This is an illegal operation - multiplication with a symbolic tag (UNDEF) which has not previously been defined.

The question mark (?) is a command to DDT to list all undefined symbols that have been used in DDT up to that point in the program.

Example:

? VALUE
UNDEF

5.4 FIELD SEPARATORS

The storage word is considered by DDT to consist of three fields: the 36-bit wholeword field; the accumulator or I/O device field; and the address field. Expressions are combined into these three fields by two operators:

Space

The space adds the expression immediately preceding it (normally an op code) into the storage word being formed. It also sets a flag so that the expression going into the address field is truncated to the rightmost 18 bits.
Single Comma

The comma does three things: the left half of the expression is added into the storage word; the right half is shifted left 23 bits (into the accumulator field) and added into the storage word. If the leftmost three bits of the storage word are ones, the comma shifts the right half expression left one more place (I/O instructions thus shift device numbers into the device field). The comma also sets the flag to truncate addresses to 18 bits.

Double Comma

Double Commas are used to separate the left and right halves of a word whose contents are expressed in halfword mode.

The address field expression is terminated by any word termination command or character.

5.5 EXPRESSION EVALUATION

Parentheses are used to denote an index field or to interchange the left and right halves of the expression inside the parentheses. DDT handles this by the following generalized procedure.

A left parenthesis stores the status of the storage-word assembler on the pushdown list and reinitializes the assembler to form a new storage word. A right parenthesis terminates the storage word and swaps its two halves to form the result inside the parentheses. This result is treated in one of two ways:

a. If +, −, ', or * immediately preceded the left parenthesis the expression is treated as a term in the larger expression being assembled and therefore may be truncated to 18 bits if part of the address field.

b. If +, −, ', or * did not immediately precede the left parenthesis, this swapped quantity is added into the storage word.

Parentheses may be nested to form subexpressions, to specify the left half of an expression, or to swap the left half of an expression into the right half.

5.6 SPECIAL SYMBOLS

The @ sign sets the indirect bit in the storage word being formed.

Example:

MOVE AC, @X
CHAPTER 6
PAPER TAPE

6.1 PAPER TAPE CONTROL

$SL This command causes DDT to punch a RIM108 loader on paper tape
RIM108 loader. (See Macro-10 manual, Chapter 6.) Thus, if
the user wishes to punch out a program on paper tape he gives a
$SL command first in order to get a loader punched on the same
tape as the program. Later when the user wishes to read in the
program from the paper tape, the hardware READ-IN feature will
load the RIM108 loader into the accumulators and then the pro-
gram will be loaded by the RIM108 loader.

FIRST<LAST TAPE This command punches out checksummed blocks in RIM108 format
2 on paper tape from consecutive locations between FIRST and LAST
address inclusively. For example, this command will punch out a
program existing in core memory in its present state of check-out
for later use.

Example:

FIRST<LAST $ TAPE

ADR$J This command punches a 2-word block that causes a transfer to
address ADR after the preceding program has been loaded from
paper tape. If ADR is not present, a JRST 4, DDT is punched as
the first word.

The following succession of steps will punch a program on paper tape ready to be used as an
independent entity.

a. $SL
b. 5000<20000 TAPE

6.000$J (Transfer to address 6000 after program is loaded.)

---

1The paper tape functions are not available in the time-sharing user mode version of DDT.
2TAPE is a single control key on the Teletype, and is identical to 1 R.

## SUMMARY OF DDT FUNCTIONS

### Type Out Modes

<table>
<thead>
<tr>
<th>To set the type-out mode to:</th>
<th>Type this</th>
<th>Sample Output(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symbolic instructions</td>
<td>$S$</td>
<td>ADD 4, TAG+1</td>
</tr>
<tr>
<td>Numeric, in current radix</td>
<td>$C$</td>
<td>ADD 4, 4002</td>
</tr>
<tr>
<td>Floating point</td>
<td>$F$</td>
<td>0.125E-3</td>
</tr>
<tr>
<td>7-bit ASCII text</td>
<td>$T$</td>
<td>PQRS</td>
</tr>
<tr>
<td>SIXBIT text</td>
<td>$6T$</td>
<td>TSROPG</td>
</tr>
<tr>
<td>RADIX50</td>
<td>$5T$</td>
<td>4 DDTEND</td>
</tr>
<tr>
<td>Halfwords, two addresses</td>
<td>$H$</td>
<td>4002, 4005</td>
</tr>
<tr>
<td>Bytes (of n bits each)</td>
<td>$NO$</td>
<td>80 COULD YIELD 0, 14, 237, 123, 0</td>
</tr>
</tbody>
</table>

### Address Modes

To set the address mode for typeout of symbolic instructions and halfwords (see examples above) to:

- Relative to symbolic address: $R$
- Absolute numeric address: $A$

### Radix Change

To change the radix of numeric type-outs to \( n \) (for \( n \geq 2 \)), type:

| $N$  | $SR$  | $2R$ COULD YIELD 11010110000001000000000001100101100 |

### Permanent vs Temporary Modes

To set a temporary type-out or address mode or a temporary radix as shown in the commands above, type:

- Temporary mode: $S$, $SC$, $S10R$

To instead set a permanent type-out or address mode or a permanent radix, in the commands above, substitute:

- Permanent mode: $S$, $SC$, $S10R$
To terminate temporary modes and
revert to permanent modes, or re-
enter DDT, type a carriage return.

Initial permanent (and temporary)

modes are

$S$S
$S$R
$S$$R$R

Examining Storage Words

To open and examine the contents of
any address in current type-out mode adr
To open a word, but inhibit the type
out of contents adr
To open and examine a word as a number
in the current radix adr
To open and examine a word as a
symbolic instruction adr
To retype the last quantity typed
(particularly used after changing
the current type-out mode)

LOC / 254020,DDTEND
LOC !
LOC (254020,3454
LOC (JRST DDTEND

Examining A Related Storage Word

To close the current open word (making
any modification typed in) and to open
the following related words, examining
them in the current type-out mode:

To examine ADR+1
To examine ADR-1

1 (line feed)
1 (or backspace,
on the Teletype
Model 37)

To examine the contents of the location
specified by the address of the last
quantity typed, and to set the location
to this address

\ (TAB)
\ (backslash)

To close the currently open word, without
opening a new word, and revert to per-
manent type-out modes.

$S$S \#5.4999646E+11
$S$T 5%0 <L

A-2
One-Time Only Typeouts

To repeat the last typeout as a number in the current radix

To repeat the last typeout as a symbolic instruction (the address part is determined by $A$ or $R$)

To type out, in the current type-out mode, the contents of the location specified by the address in the open instruction word, and to open that location, but not move the location pointer.

To type out, as a number, the contents of the location specified by the open instruction word and to open that location, but not move the location pointer.

To type out, as a symbolic instruction, the contents of the location specified by the open instruction word, and to open that word, but not move the location pointer.

Typing In

Current type-out modes do not affect typing in, instead

To type in a symbolic instruction

ADD AC1, #DATE(17)

To type in half words, separate the left and right halves by two commas.

402, 403

To type in octal values

1234

To type in a fixed-point decimal integer

99

To type in a floating-point number

101.11
77.9E+2

To type in up to five 7-bit PDP-10 ASCII characters, left justified, delimited by any printing character. 

"/ABCDE/ (/ is delimiter)

To type in one PDP-10 ASCII character, right justified

"A" ($ must be ALT MODE)

To type in up to six SIXBIT characters, left justified, delimited by any printing character

"$ABCDEFGA (A is delimiter)

To type in one SIXBIT character, right justified

"$"0$ ($ must be ALT MODE)
Symbols

To permit reference to local symbols within a program titled name$ type name$:

To insert or redefine a symbol in the symbol table and give it the value n<symbol> type 14<TABL3:

To insert or redefine a symbol in the symbol table, and give it a value equal to the location pointer (.), type symbol:

To delete a symbol from the symbol table symbol$SK LPCT$SK

To kill a symbol for typeouts (but still permit it to be used for typing in) symbol$K TBITS$K

To perform $K on the last symbol typed out and then to retype the last quantity $D

To declare a symbol whose value is to be defined later symbol# INST AJAX#

To type out a list of all undefined symbols (which were created by #) type ?

Special DDT Symbols

To represent the address of the location pointer . (point)

To represent the last quantity typed $Q

To represent the indirect address bit @

To represent the address of the search mask $M

To represent the address of the saved flags, etc. (see Appendix D) $1

To represent the pointers associated with the nth breakpoint $nB

Arithmetic Operators Permitted in Forming Expressions

Two's complement addition +

Two's complement subtraction -

Integer multiplication *

Integer division (remainder discarded) ' (apostrophe)
Field Delimiters In Symbolic Type-Ins

To delimit op-code name, type one or more spaces.

To delimit accumulator field, type

To delimit two halfwords, type left , , right

To delimit index register ( )

Breakpoints

To set a specific breakpoint $ n (1 \leq n \leq 8)$

<table>
<thead>
<tr>

Conditional Breakpoints

To insert a conditional instruction (INST), or call a conditional routine, when breakpoint $ n$ is reached.

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$ n B+1 /$</td>
<td>INST</td>
<td></td>
</tr>
<tr>
<td>$ 2 B+1 /$</td>
<td>CAI E</td>
<td></td>
</tr>
</tbody>
</table>

If the conditional instruction does not cause a skip, the proceed counter is decremented and checked. If the proceed count \( \leq 0 \), a break occurs.

If the conditional instruction or subroutine causes one skip, a break occurs.

If the conditional instruction or subroutine causes two skips, execution of the program proceeds.
Starting the Program

To start at the starting address in JOBSA
\[ \text{SG} \]

To start, or continue, at a specified address
\[ \text{adr} \ SG \]

To execute an instruction
\[ \text{inst} \ SX \]

\[ \text{JRST 2, @JOBOPC$X} \]
returns to program after 1C and DDT commands

Searching

To set a lower limit (a), an upper limit (b), a word to be searched for (c), and search for that word
\[ a<b>c<W \]
\[ 200<250>05W \]

To set limits and search for a not-word
\[ a<b>c<N \]
\[ 200<731>05N \]

To set limits and search for an effective address
\[ a<b>c<E \]
\[ 401<471>LOC+6SE \]

To examine the mask used in searches (initially contains all ones)
\[ M/ \]
\[ M/ -1 \]

To insert another quantity n in the mask
\[ nM \]
\[ 77700777777777M \]

Instruction Execution

\[ SU \]
\[ $Y \]

Zeroing Memory

To zero memory, except DDT, locations 20-137, and the symbol table
\[ ZZ \]

To zero memory locations FIRST through LAST inclusive
\[ \text{FIRST<LAST } ZZ \]

Special Characters Used in DDT Typeouts

Breakpoint stops
- Break caused by conditional break instruction.
  \[ > \]
- Break because proceed counter < 0
  \[ > > \]
- Undefined symbol cannot be assembled
  \[ U \]
- Half-word type-outs
  \[ \text{left} , , \text{right} \]
  \[ 401 , , 402 \]
Unnormalized floating-point number

To indicate an integer is decimal.
The decimal point is printed

Illegal command

If all eight breakpoints have been assigned

RUBOUT echo

\textbf{Paper Tape Commands (Available only in EDDT)}

To punch a RIM10B loader

\$L

To punch checksummed data blocks where ADR1 is the first, and
ADR2 is the last location of the data

\(\text{ADR1<ADR2 (TAPE)}\)
\(\text{(TAPE) is IR}\)

To punch a one-word block to cause a transfer to adr after the preceding program has been loaded from paper tape

\text{adr$J}$
APPENDIX B
EXECUTIVE MODE DEBUGGING (EDDT)

A special version of DDT, called EDDT, is available for debugging programs in the executive mode of the PDP-10. In general, EDDT performs the same debugging functions as user mode DDT. All of the paper tape commands are available in EDDT (those in DDT are marked by an asterisk in Chapter 5). The paper tape I/O routines in EDDT are optional at assembly time.

EDDT is used to debug Monitor programs, diagnostic programs, and other executive (or privileged) programs. EDDT performs its own I/O on a Teletype and controls the Priority Interrupt system. It does not check JOBREL for boundary limits as DDT does.

In EDDT the symbol table pointer is in location 36. EDDT does not check location 37, which contains the highest valid address, before address examination. If the NXM Stop switch is ON, the machine will hang up if nonexistent memory is referenced. If this happens, EDDT may be restarted by pressing START, or the CONTINUE switch may be pressed.

The first address of EDDT is DDT; the last is DDTEND.

The $SZ command will not zero locations 20 through 37. (In the user mode version, $SZ does not zero locations 20 through 137. See Section 4.5.)
APPENDIX C
STORAGE MAP FOR DDT

The permanent symbol table, which contains all PDP-10 instructions and Monitor UU Os, is an integral part of DDT.

If the user's symbol table is overwritten, DDT can still interpret all instructions and UUOs. It will not interpret /O device mnemonics, internal $ symbols ($M,$I, $1B through $88, DDT and DDTEND or the following:

JOV
JEN
HALT
APPENDIX D
OPERATING ENVIRONMENT

Entering and Leaving DDT

When control is transferred to DDT, the state of the machine is saved inside DDT:

a. The accumulators are saved.

b. The status of the priority interrupt system (the result of a CONI PI, $1) is stored in the right half of register $1.

c. The central processor flags are saved in the left half of register $1.

d. The PI channels are turned off (by a CONO PI, @($1+1)) if they have a bit in register $1+1.

e. The Teletype PI channel is saved in the right half of register $1+2. The teletype buffer is saved in the left half of $1+2 but can never be restored. The character in the output buffer will have been typed on the Teletype.

f. Then using the Monitor command DDT 2, the old PC is saved in the right half of location JOBOPC, with the flags in the left half.

When execution of a program is restarted, the following happens:

a. The accumulators are restored.

b. Those PI channels which were on (when DDT was entered) and which have a bit equal to 1 in register $1+1 are turned on.

\[
(C(\overline{SI}_R) \land C(\overline{SI+1}_R)) \land V2000 \Rrightarrow \text{PI SYSTEM}
\]

(logical AND (\land), logical OR (\lor))

c. The Teletype PI channel is restored.

0 \rightarrow \text{TTI DONE} \rightarrow \text{TTI BUSY} \rightarrow \text{TTO BUSY}

TTO done is set to 1 if either TTO busy or TTO done was on when DDT was entered. Otherwise, 0 \rightarrow \text{TTO done}.

d. The processor flags are restored from the left half of register $1.

e. To return to a program interrupted by INC, the user types:

\text{J\RST 2, P JOBOPC\$X TO RESTORE THE PC AND FLAGS}.

\text{\textsuperscript{1}Functions not available in the time-sharing user mode.}
Loading and Saving DDT

How to load and save DDT.SAV (PDP-10) or DDT.DMP (PDP-6) in 2K of core:

<table>
<thead>
<tr>
<th>Instructions</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load DDT in 4K of core.</td>
<td><code>^R LOADER 4 DTA1:DDT,140G (ALTMODE)</code></td>
</tr>
<tr>
<td>Enter DDT.</td>
<td><code>^ST</code></td>
</tr>
<tr>
<td>Type out, in halfword mode, the contents of JOBSYM.</td>
<td><code>$SH JOBSYM/ -162,,7616</code></td>
</tr>
<tr>
<td>Open register 6 and put (JOBSYM)RH into the left half of 6; put (JOBSYM)RL - 4000B into the right of 6.</td>
<td><code>6T 7616,,3616</code></td>
</tr>
<tr>
<td>Perform a block transfer until you reach address 3777B.</td>
<td><code>BLT 6,3777BX</code></td>
</tr>
<tr>
<td>Open up JOBSYM. Leave the left half as is, and change the right half to 4000B less than it was.</td>
<td><code>JOBSYM/ -162,,3616</code></td>
</tr>
<tr>
<td>Zero memory except DDT.</td>
<td><code>$SZ</code></td>
</tr>
<tr>
<td>Open up JOBSA and check that left half = DDTEND; if not, change left half to DDTEND.</td>
<td><code>JOBSA/ 0,,DDT DDTEND,,DDT</code></td>
</tr>
<tr>
<td>Change back to symbol type-out mode.</td>
<td><code>$SS</code></td>
</tr>
<tr>
<td>Return to the Monitor.</td>
<td><code>^C</code></td>
</tr>
<tr>
<td>Reduce core to 2K.</td>
<td><code>^CORE 2</code></td>
</tr>
<tr>
<td>Reenter DDT.</td>
<td><code>^ST</code></td>
</tr>
<tr>
<td>CHECK JOBREL.</td>
<td><code>JOBREL/ 3777</code></td>
</tr>
<tr>
<td>Return to the Monitor.</td>
<td><code>^C</code></td>
</tr>
<tr>
<td>Save DDT.</td>
<td><code>^SAVE DTA1 DDT</code></td>
</tr>
</tbody>
</table>

Explanation - The DDT saved file must be saved in 2K (minimum amount of core needed for it). Also, a starting address must be set up for DDT as location 140. To get DDT into 2K, the DDT symbol table must be moved down to the upper end of the first 2K of core. Any unused locations in DDT should be set to zero ($SZ$) and JOBSYM should be set to the new location of the start of the DDT symbol table. Before saving the resulting file, a CORE 2 request should be given to the Monitor to ensure that DDT is saved as a 2K core image.
