# A source handbook for Digital Equipment Corporation LSI-11-compatible products 

WILLIAM L. PALYA<br>St. Joseph's College, Rensselaer, Indiana 47978

#### Abstract

Digital Equipment Corporation's LSI-11-compatible products are listed according to general type. Prices, delivery dates, and descriptive data are included. Sources and costs of generalpurpose systems that will run RT-11 are also provided.

The LSI-11 is the least expensive of the very popular PDP-11 family of computers from Digital Equipment Corporation (DEC). In addition to having the powerful architecture of the PDP-11, the LSI-11 will execute much of the enormous quantity of software available for the PDP-11. An excellent operating system, RT-11 also runs on the LSI-11; RT-11 is designed for a small laboratory environment and does virtually everything that is needed to conveniently coordinate a computer system with relatively simple commands.

The primary purpose of this paper is to indicate availability, summarize features, and provide comparative prices of LSI-11-compatible items. These offerings, specifications, and prices, however, change frequently and sources should be consulted. Additional considerations are also important. Frequently overlooked factors are delivery dates, whether or not additional power supplies or cables are required, software compatibility and support, and the degree and source of hardware support. General engineering support for DEC's LSI-11 products can be obtained through their hotline ( $800-225-9220$ ). Every attempt has been made to assure an accurate description and price. However, no responsibility is assumed by the author or publisher for accuracy or completeness. Readers should consult sources concerning all information.

Prices are typically given as the list unit price. However, several system houses have negotiable prices. It is possible for educational institutions to obtain discounts of as much as $25 \%$ from some vendors. When you decide on a system and receive a quote, by all means, let the competition have a chance to negotiate.

The DEC prices are listed as: (1) list price, the price charged by the regional sales offices; (2) catalogue price, the price charged by the DEC Direct Sales Division, if they bill you; and (3) cash price, the price charged by the DEC Direct Sales Division if you send cash. When two prices are given for other suppliers, the second price is a cash or COD cost.

[^0]
## SYSTEMS

The typical laboratory system includes a central processing unit (CPU), 28 K of memory, one parallel input-output ( $1 / 0$ ) interface, one serial $1 / O$ interface, one terminator, one bootstrap, one floppy-disk controller, two floppy-disk drives, an 8 -slot backplane, an enclosure, power supply, RT-11, and FORTRAN. A terminal costs an additional $\$ 300$ to $\$ 3,000$. Table 1 presents systems configured as a "typical" system for comparison purposes. These systems are guaranteed to be complete, configured, and to run RT-11 as shipped by the supplier (less only the terminal). This comparison configuration does not take advantage of the special pricing available for the "standard" system of each supplier, however, nor does it list systems not normally configurable in this way.

## CENTRAL PROCESSING UNITS

It is within reason for someone with only moderate technical skill to configure his own system and thereby save a considerable amount of money. The initial requirement is an LSI-11 CPU. Two versions are presently available. The original LSI-11 is on a $23 \times 27 \mathrm{~cm}$ board. It has four edge connectors and is referred to as a "quad" height board. The LSI-11/2 CPU is contained on a $23 \times 13 \mathrm{~cm}$ board. It has two edge connectors and is referred to as a "dual" height board.

There are several differences between the boards in addition to size. The original board contained 4 K of memory and simple refresh circuitry for the memory. Both have now been removed and put on a separate memory board. The CPU clock logic has been changed to a crystal for improved accuracy. The required external "wake-up" circuitry has also been eliminated. This is the external logic (normally contained in the DEC power supply) that sequences the CPU into the run state. This modification allows purchasers to build a system from bare boards with no additional logic. The KD11-R and the KD11-J are special-purpose 2-quad board configurations. The KD11-R contains 16 K of semiconductor and the KD11-J contains 4 K of core
memory. Table 2 indicates various sources for LSI-11 CPU boards, their prices, and delivery dates.

## EXTENDED ARITHMETIC ELEMENT

The CPU boards contain an additional empty socket into which a special chip can be plugged to increase the speed of multiplication, division, and floatingpoint calculations. This extended arithmetic element chip is especially useful when arithmetic operations are needed in real-time. Table 3 presents sources for the extended arithmetic chip.

## BACKPLANES

The CPU and other cards plug into and are thereby interconnected through a backplane. Backplanes may not be jumpered together indefinitely nor indiscriminately, however. The LSI-11 is limited to driving a signal through between 9 and 12 quad slots. The exact figure is determined by the backplane configuration. Considering the signal reflection problems and the cost of expanding a backplane through jumpers, it is advisable to purchase a large backplane initially if expansion is contemplated. The LSI-11 is also limited to driving 15 "unit loads." Each board in the backplane that uses the DEC recommended interface chips, whether dual or quad height, generally represents somewhere between .5 and 1 unit load to the bus. (See the discussion with Table 20 if more than 15-20 boards are needed.) Table 4 presents suppliers of backplanes.

## POWER SUPPLIES

Logic in most computer circuits requires +5 V , $\pm 5 \%$ with $.15-\mathrm{V}$ ripple. This supply provides most of the current in any system. In addition, DEC boards also require $+12 \mathrm{~V}, \pm 3 \%$ with $.35-\mathrm{V}$ ripple. Analog circuitry usually requires $\pm 15 \mathrm{~V}, \pm 1 \%$ with $10-\mathrm{mV}$ ripple. The accuracy of this power supply determines to a large extent the accuracy of the analog circuitry. Two other voltages that are occasionally required for boards without onboard converters and for lab-built boards are $-12 \mathrm{~V}, \pm 3 \%$ with $.15-\mathrm{V}$ ripple, and -5 V , $\pm 5 \%$ with $.05-\mathrm{V}$ ripple. The easiest way to determine the required capacity of each supply while providing sufficient current for expansion is to calculate the current required by each board to be used from its specification sheet then double that amount. If a shopmade or surplus power supply is used, an overvoltage protector (OVP) should be included. Table 5 lists power supplies available through system houses or LSI-11 vendors. DEC and several other suppliers include in the power supply the necessary "wake-up circuitry" (WU) to initialize the LSI-11. Other suppliers provide the power-up sequencer as a separate unit. Separate power-up sequencers are presented in Table 21; with them, any power supply may be used.

## ENCLOSURES WITH BACKPLANES

The system is most easily and safely assembled into a rack-mounting enclosure, which can be easily shopbuilt or purchased from various sources. Table 6 lists enclosures with backplanes offered by system houses. These enclosures do not necessarily accommodate an internally mounted power supply from a different supplier.

## MEMORY

The LSI-11 is capable of addressing 32 K of memory with the upper 4 K generally reserved for peripheral devices. Memory chips can now be manufactured in 16 K increments, resulting in 32 K boards rather than the conventional 28 K , which is typically considered a complete memory. Some of the upper 4 K memory space can be used, however, as unsupported memory when it is available. Semiconductor memory manufacturing technology is quickly developing, with a resultant rapid decrease in cost and size. Memory prices, therefore, should be checked within a month of purchase, and purchase of memory should be delayed whenever possible. Suppliers of semiconductor memories (RAMs) are listed in Table 7. These are typically dynamic memories, which are compact and inexpensive but must be frequently "refreshed" to retain information. (See discussion with Table 14 for discussion of methods.) Dynamic memory boards with onboard refresh do not require the use of the bus for refresh and save the purchase of an additional "refresher" board. Semiconductor memories that do not require refresh are static memories and are indicated as such.

Table 8 lists special-purpose memories. Core memory retains information when the machine is powered down. Several types of semiconductor memories also retain information when the power is removed. Read-only memory (ROM) is permanently programmed during manufacture. Programmable read-only memory (PROM) allows the user to write the information into the chips with the use of a special programmer. Simple or fusible link PROM is permanently programmed once written, whereas UVPROM allows the user to erase the memory with ultraviolet light.

## INPUT-OUTPUT

These boards take the bits that are set in the computer word and set output lines, or sense signals on input lines and set bits in the computer word. I/O is accomplished in either a serial or parallel fashion. Serial I/O is for low-speed applications, such as terminals and phone lines, in which data is transmitted 1 bit at a time. Table 9 lists suppliers of serial boards.

Parallel I/O is when information is transferred 16 bits at a time, as in digital on-line control of experiments. Additional circuitry is required to drive relays, unless the board is specifically designed to drive high-current
devices. The extra circuitry for the additional drivers is straightforward, however, and can be easily constructed. Suppliers of parallel boards are listed in Table 10.

## OPERATING SYSTEMS AND SOFTWARE

Software is supplied on various media, with and without source listings, and with different levels of support and updating service. The RT-11, mini UNIX, mini FORTH, and PASCAL operating systems and various software packages such as FORTRAN, FOCAL, APL, TSX, BASIC, and others are available as indicated in Table 11.

## FLOPPY DISKS

In order to run the RT-11 operating system, a mass storage device such as a floppy disk is required. A disk subsystem contains a disk drive and a controller. Some vendors sell only the controller, some supply both the controller and the drive. Table 12 lists only those controllers or disk subsystems that plug into an LSI-11 backplane, are compatible with unmodified RT-11 disk handlers, and conform to the single-density singlesided DEC media format. Table 13 is a list of floppydisk controllers and disk systems that plug into the LSI-11 but do not run under an unmodified RT-11, or are not the single-density single-sided DEC format. DEC format is limited to 235 K bytes/diskette, whereas double-density double-sided diskettes can contain 1.2 megabytes. Some of the controllers listed in Table 13 require only minimal software changes and/or have conversion software available from the vendor.

## HARD DISKS

In addition to the relatively inexpensive flexible or floppy disks, hard-surface disks are available. Their capacity is from 20 to 100 times that of a single DECformat floppy, and they have a much faster data rate. Table 14 presents suppliers of hard-disk controllers and/or disk subsystems that plug into the LSI-11 backplane.

## TERMINATORS

A terminator that suppresses signal reflection in multibackplane configurations and increases noise immunity is frequently used at the end of the bus when it has been extended through flat cable. It is not as crucial in single large backplanes. It is usually implemented as a board, but the ADAC, Andromeda, and DEC LSI-11/2 backplanes incorporate built-in sockets for terminator chips. It takes little to terminate the bus, so other functions are frequently available on the same
board. Table 15 presents suppliers of terminator boards. Major boards such as disk controllers that include a terminator are listed with those boards.

A typical function that is added to a terminator board is memory refresh. When at least one memory board does not have onboard refresh, this function must be provided by some other board. This can be accomplished in either of two ways. The LSI-11 (KD11-F) CPU board has a refresh circuit that stops the processor and refreshes the entire memory at one time. This takes 160 microsec every 2 msec regardless of the amount of memory implemented. A different "interleaved" memory-refresh circuitry is available in the REV series terminators. The refresh is interleaved between CPU operations such that only 1.2 microsec every 30 microsec are used. In this way important highspeed events such as direct memory access (DMA) (see discussion with Table 21 for explanation) or fast interrupt servicing are not precluded. However, the memory-refresh card must be physically closer to the CPU than any other DMA device. If a DMA device is required and the memory-refresh circuitry is with the terminator, the DMA device frequently may be positioned after the terminator-refresh board, but it should be avoided when possible.

## OTHER STORAGE MEDIA

Magnetic tape, cartridge tape, LINCtape or DECtape, and paper tape are other types of storage media. These tapes are less expensive and have a greater capacity than disks, but they are slower. LINCtape or DECtape is file structured in the same way as a disk and can therefore be used as a random-access device just as a disk.

The other storage media listed in this table are sequential access and may not be randomly accessed. Magnetic tape provides a great deal of relatively inexpensive storage. Tape cartridges are more convenient, but they provide only about as much storage as a small hard-surface disk. Paper tape is the least expensive and the slowest. It has traditionally been the universal media, in that at one time virtually every system had an ASR33 Teletype. Table 16 lists suppliers for each type of storage device.

## ANALOG CONVERTERS

Frequently, analog information such as voltage levels must be sensed or produced by the computer. This is done by means of analog-to-digital (A/D) and digital-toanalog (D/A) converters, respectively. These boards plug into the LSI-11 and are used very much like parallel and serial I/O boards (Table 17). In this case, however, digital bit patterns represent voltages. Some analog
boards do not have onboard voltage converters and require either additional system power supplies or the purchase of voltage converters as an option.

## CLOCKS

Programmable real-time clocks allow the user to set and read a "memory location" as a time that automatically increments or decrements at a specified rate. These clocks can also be configured to provide an interrupt at given intervals or to measure time intervals of external events. This is a great asset when timekeeping functions are important and great accuracy or many timing-related operations are necessary. Table 18 presents suppliers of real-time clocks.

## GRAPHICS

Graphic display systems create figures and images on a cathode-ray tube (CRT). The two major classes of graphic display systems are the raster scan and the XY display. A home television is a raster-scan CRT. In raster-scan displays, the electron beam scans the screen automatically and the computer turns the beam off and on as it passes the appropriate points. An XY display works on the same principle as an "Etch-a-Sketch." XY displays move the beam only where it is needed in the image. There are two types of XY displays, point plot and vector. In XY point-plot displays, the image is created as a series of independently specified points. In vector graphics a line is drawn between a start position and a stop position. Raster-scan CRT displays are less expensive than comparable XY CRT displays.

In general, a great deal of memory and/or computer power is required for graphics when the display must be continually maintained or refreshed by the graphics controller. For example, a raster-scan image with a resolution of 512 by 512 points similar to a highcontrast television picture requires 16 K of 16 -bit words. With a storage CRT, once the image is drawn, little further overhead is necessary. Table 19 lists the graphics controllers that plug into the LSI-11.

## BUS REPEATERS AND CONVERTERS

When the drive capability of the CPU is exceeded, a "bus repeater" is required. The bus repeater simply amplifies or redrives the signals to and from the CPU. The unassisted CPU can drive 15 unit loads. A bus repeater as the 15 th unit load allows the use of additional unit loads on the bus.

Boards are available to plug into the LSI-11 and translate the Qbus (LSI-11) into Unibus (PDP-11) protocol. The Qbus-to-Unibus converter enables the LSI-11 to take advantage of the enormous number of peripheral controllers that have been developed or are currently in use for the more established PDP-11s.

A bus protocol that is increasing in popularity is the general-purpose interface bus (GPIB) or IEEE-488 bus: A growing variety of instruments and controllers are available that plug into the IEEE- 488 bus.

## MISCELLANEOUS INTERFACES

Table 21 lists some miscellaneous interfaces that plug into the LSI-11. These include DMA interface controllers for various peripherals. A DMA controller is an intelligent I/O card that works independently of the CPU, thus freeing the CPU from the overhead of performing certain types of I/O operations. DMA is typically used for high-speed data transfers. Once loaded with the addresses of a block of memory, the device transfers the entire block before requiring service by the CPU again. DMA transfers can interfere with any bus memory-refresh operation and therefore must be carefully considered when configuring the refresh hardware and when writing the DMA software.

For custom-circuit applications, there are many classes of blank boards or boards that provide only the bus interface logic. These range from small undrilled boards to large wire-wrappable boards already containing DMA logic. Table 22 lists suppliers of these boards.

## CABLES

Premade cables can be expensive; however, 40 conductor flat cables can be easily and economically made by the user. Lab-built cables cost about $\$ 1 / \mathrm{ft}$, plus $\$ 10$ for the connectors. The flat cable can be cut with an ordinary scissors and the connector can be installed by inserting the flat cables in the provided slot and then squeezing the connector shut in a vise. Reels of cable and "insulation displacement" connectors are available from many sources. Twisted-pair cable is also available with flat spots every few feet so that common insulation displacement connectors can be used. Some representative premade cables are presented in Table 23.

Table 24 lists the addresses and telephone numbers of the vendors cited in the previous tables. Known information concerning the warranty period and educational discounts are also noted.

Mini-FORTH, multitask, virtual memory operating system, optimized for proces control and data acquisition; includes FORTH language, disk utility, editor, documentor, file handler; requires 6 K bytes, RS-232 CRT terminal and one disk; includes documentation, sources, on-site installation and training.

Fully supported by General Robotics. BASIC language processor.
FORTRAN IV compiler.
Multiuser BASIC.
APL interpreter.
Timesharing executive software

PASCAL package including compiler, demo library and debugger.

DEC QJV10-CB (paper-tape operating system).

DEC QJ960 (FORTRAN subroutines).
DEC ZJ215-RY (diagnostics on floppy). DEC ZJV01-RB (paper-tape diagnostics). CAMAC FORTRAN, callable, singleaction statements.

PASCAL operating system includes PASCAL compiler, 2 editors, filer, debug package, BASIC compiler, utility pro grams. Includes users manual, sources, documentation, and support.
Same as above, except no detailed system documentation or continued support.

Table 12
Floppy-Disk Drives and/or Controllers
(DEC Single-Side, Single-Density, Media, and RT-11 Handler Compatible)

| Model | Price | Delivery | Description |
| :---: | :---: | :---: | :---: |
| ANDROMEDA |  |  |  |
| FDC11 | 850 | Stock-30 | Controller for up to 4 single-sided, |
|  |  |  | single-density, Pertec FD400 or FD500 |
|  |  |  | drives (I personality card, PC400, |
|  |  |  | required per drive, $\$ 80$ each), hard- |
|  |  |  | formatter, dual board with cable. |
| FDCII-A | 885 | Stock-30 | Same as FDC1 1 but for Shugart SA-800-2 |
|  |  |  | or equivalent drives, no personality card required, |
| FDC11-B | 895 | Stock-30 | Same as FDC11-A except for Shugart |
|  |  |  | SA-850 double-sided drives or equivalent, compatible in single-side mode only. |
| PC400 | 80 | Stock-30 | Personality card for use with FDC11 |
|  |  |  | and Pertec FD400/500. |
| FD400 | 525 | Stock-30 | Disk drive, Pertec (DC motor). |
| FDS00 | 525 | Stock-30 | Disk drive, Pertec (AC motor). |
| SA-800-2 | 560 | Stock-30 | Disk drive, Shugart. |
| SA-850 | 640 | TBA | Disk drive, Shugart, double sided. |
| DFDS | 3095 | 30 | Subsystem with 2 single-sided, single- |
|  |  |  | density Pertec drives, full controls and indicator lights, formatter, write protect, |
|  |  |  | dual board. |
| DFDS-A | 3095 | 30 |  |
|  |  |  | and only write protect and boot switches, formatter, dual board. |
| DFDS-B | 3295 | 30 | Subsystem with 2 double-sided, single- |
|  |  |  | density Shugart 850 drives, DEC media |
|  |  |  | and handler compatible in single-sided |
|  |  |  | mode only, double-sided handler in- |
|  |  |  | cluded, formatter, write protect, dual board. |
| CRDS |  |  |  |
| FD-11 | 2875 | 30 | Subsystem with 2 single-sided, single- |
|  |  |  | density Shugart SA800 drives, bootstrap |
|  |  |  | in PROM, write-protect switch, unit- |
|  |  |  | select switches, microprocessor controller on quad board, formatter. |
| FD-11-X | 3425 | TBA | Same as above but with double-sided |
|  |  |  | Shugart 850 drives, media and handler |
|  |  |  | compatible in single-side mode only. |

COMPUTER
MARKETING

Subsystem with 2 single-sided, singledensity Shugart SA800 drives, bootstrap in PROM, write-protect switch, unitselect switches, microprocessor controller on quad board, formatter.
Same as above but with double-sided Shugart 850 drives, compatible in singleside mode only.

Subsystems with single-sided, singledensity Shugart SA800-2 drives, writeprotect switches, hardware bootstrap, bus terminators, memory refresher, formatter, dual board.
Single drive system.
Dual drive system.
Triple drive system.
Subsystem with 2 single-sided, singledensity Shugart SA800-2 drives, for-
