Author's Note

These programs have been thoroughly tested and are believed to be correct. If you find something not to your liking let us know. We welcome your comments, criticisms or questions. Please call or write if you experience any problems.

Robert Doolittle Echelon Team Member 1290 Monument Street Telephone 213/454-8270 Pacific Palisades, CA 90272

These programs translate assembly source code from Intel extended 8080 to Zilog Z-80 mnemonics (ITOZ) and vice versa (ZTOI). The output source file is written to disk and is completely formatted and ready for assembly. The extended 8080 set is that defined by Digital Research in their macro library Z80.LIB furnished with their macro assembler MAC. Please note that if your source programs use only the 8080 subset of the Z-80 instructions then you need not be concerned with the Z80.LIB extensions.

The use of ITOZ and ZTOI are nearly identical. Therefore in what follows we shall just refer to ITOZ with the understanding that it also applies to ZTOI except where noted.

To execute ITOZ for translation of an 8080 source program to Zilog Z-80 mnemonics the Z-System (and CP/M) command line format is:

A>ITOZ ifilename[filetype][/O] [ofilename][filetype]

where the parameters in square brackets are optional.

ifilename=input source file name ofilename=output source file name /O=options as described below

To maintain compatibility with some assemblers two switch options are available. The slash (/) must immediately follow the input file name or filetype if used. Only one slash is necessary for either or both options.

The "c" option will add a colon after a label if one does not already exist. The "s" option will convert asterisks, used as comment line delimiters, to semicolons in the output file. To invoke both options, for example, the format would be:

/cs or /sc

If you are translating a file that uses a double colon to represent a public label do not use the "c" switch.

An optional output file name is also permitted on the command line. If this optional name is omitted then the default output file name for ITOZ is ZLG.ASM and for ZTOI is X80.ASM.

CP/M is a registered trademark of Digital Research; Z-System is a trademark of Echelon.

INPUT FILE FORMAT RULES

Certain input source file format rules must be followed to obtain a successful translation. Many of these are dictated by common assembler syntax rules. The rules are as follows:

1. Only one instruction per line is permitted

- 2. All instructions must be in upper case
- Each line must terminate in a carriage return and line feed
- 4. No line numbers are permitted in this version
- 5. Lines must be less than 128 characters long including comments
- 6. All labels must start in column one
- 7. The mnemonic or instruction field must be preceded by at least one space or tab if no label is present
- 8. There must be at least one space or tab between the end of a label and the beginning of the instruction unless the label ends in a colon
- 9. EQU and SET pseudo-op statements may begin in any column
- 10. Other pseudo-ops or macro names must begin as defined for instructions in Rule 7
- 11. Comment lines must be preceded by a semicolon or asterisk and may begin in any column
- 12. Comments following instructions on the same line must also begin with a semicolon or asterisk and must be preceded by at least one space or tab only if the asterisk is used

Blank lines, as well as blank lines following a label, are supported.

Due to the variety of assembler pseudo-ops some compromises had to be made. There is a logical problem with pseudo-ops starting with an asterisk and comment lines delimited by an asterisk. This is solved in these translators by the following additional rule:

13. If pseudo-ops are used which start with an asterisk then a label must be used on the same line. The label, of course, may be a dummy. In addition, actual comment lines following a label must be delimited by a semicolon.

When program execution begins ITOZ will print a message on the terminal indicating that the translation is underway. If an unrecognizable instruction is encountered a syntax error message is displayed at the console along with a line number indicator. This line is also flagged in the output file by the comment line "FOLLOWING INSTRUCTION NOT RECOGNIZED." The translator makes no attempt to translate this line but simply copies it to the output file.

Most of the common pseudo-ops are included in the translator's internal tables. If you get a syntax error for a pseudo-op or macro name which appears in your input source file you should then run the utility, ADNAME.COM as described below. This will prevent future occurrences of this error. As noted below, this utility does <u>not</u> translate or, more accurately, it results in a one-to-one translation (exact copy) of entire line.

In all CPU instructions that involve an index register displacement, the translators will interpret the explicit lack of a displacement argument to imply the value 0.

This utility permits the user to add custom macro names or pseudo-ops to the translator's internal tables. It will operate on either ITOZ.COM or ZTOI.COM. It will also operate on either of these files if they have been renamed. Please note that no translation occurs for these names. The use of ADNAME permits the translators to recognize these names and to copy the line

from the input file to the output file without generating an error message. If you experience difficulty with assembly of a translated file it may be necessary to edit the translated file to correct for the particular pseudo-ops used by your assembler. The command line format for ADNAME is:

A>ADNAME filename.COM

where 'filename' is ITOZ, ZTOI, or whatever you may have renamed them. The program will then prompt you for the new names to be entered. Each entry is terminated by a carriage return. A blank line (CR) terminates the program. The old file is renamed with the same filename and with a filetype of BAK. The new file is renamed with the same filename and with a filetype of COM. The new COM file will include your new names. If you wish you may erase the BAK file. We strongly recommend, however, that you always keep a backup copy of the original files.

The space allocated in the translators for this function is 200 bytes. If N is the number of new names and C is the total number of characters in the new names then 2*N+C must be <= 200. Attempts to exceed this number will not be accepted and a warning message will be issued.

ADNAME may be used on the current COM file as often as you please. Any new names will be added to those already included and a new COM file and new BAK file will be created.

These translators use an extended 8080 mnemonic set which is similar to the Technical Design Laboratories (TDL) mnemonics. All Intel 8080 mnemonics are preserved. The Z-80 peculiar instructions differ from the ZILOG mnemonics as shown in the accompanying table. This mnemonic set is identical to that released by Digital Research as Z80.LIB to be used with their CP/M "MAC" Macro Assembler. The following conventions are used in the table.

r - any register or memory

rr - any register pair or stack pointer

nn - 8 bit immediate data (0 to 255)

d - 8 bit signed displacement (-128 to 127)

nnnn - 16 bit address or immediate data (0 to 65535)

b - bit number (0 to 7, 7 is most significant)

addr - 16 bit address within PC+127 through PC-128

In cases involving a displacement, d, this parameter is always last one in operand field.

These programs translate assembly source code from Intel extended 8080 to TDL/CDL (Xitan) mnemonics (ITOT) and vice versa (TTOI). The output source file is written to disk and is completely formatted and ready for assembly. The extended 8080 set is that defined by Digital Research in their macro library Z80.LIB furnished with their macro assembler MAC. Please note that if your source programs use only the 8080 subset of the Z-80 instructions then you need not be concerned with the Z80.LIB extensions.

The use of ITOT and TTOI are nearly identical. Therefore in what follows we shall just refer to ITOT with the understanding that it also applies to TTOI except where noted.

To execute ITOT for translation of an 8080 source program to TDL/CDL mnemonics the Z-System (and CP/M) command line format is:

A ITOT ifilename[filetype] [ofilename][filetype]

where the parameters in square brackets are optional.

ifilename=input source file name ofilename=output source file name

The optional output file name defaults to X80.ASM for TTOI and to TDL.ASM for ITOT

ITOT will automatically insert colons after labels, if not present, since the TDL/CDL assembler requires them. It will also convert any asterisks, used as comment delimiters, to semicolons for the same reason. Furthermore, ITOT will automatically supply an .END statement if required.

Certain input source file format rules must be followed to obtain a successful translation. Many of these are dictated by common assembler syntax rules. The rules are as follows:

- 1. Only one instruction per line is permitted
- 2. All instructions must be in upper case
- Each line must terminate in a carriage return and line feed
- 4. No line numbers are permitted in this version
- 5. Lines must be less than 128 characters long including comments
- 6. All labels must start in column one
- 7. The mnemonic or instruction field must be preceded by at least one space or tab if no label is present
- 8. There must be at least one space or tab between the end of a label and the beginning of the instruction unless the label ends in a colon
- 9. EQU and SET pseudo-op statements may begin in any column
- 10. Other pseudo-ops or macro names must begin as defined for instructions in Rule 7
- 11. Comment lines must be preceded by a semicolon or asterisk and may begin in any column. (See also Rule 13)
- 12. Comments following instructions on the same line must also begin with a semicolon or asterisk and must be preceded by at least one space or tab only if the asterisk is used

Blank lines, as well as blank lines following a label, are supported.

Due to the variety of assembler pseudo-ops some compromises had to be made. There is a logical problem with pseudo-ops starting with an asterisk and comment lines delimited by an asterisk. This is solved in these translators by the following additional rule:

13. If pseudo-ops are used which start with an asterisk then a label must be used on the same line. The label may, of course, be a dummy. In addition, actual comment lines following a label must be delimited by a semicolon.

When program execution begins ITOT will print a message on the terminal indicating that the translation is underway. If an unrecognizable instruction is encountered a syntax error message is displayed at the console along with a line number indicator. This line is also flagged in the output file by the comment line "FOLLOWING INSTRUCTION NOT RECOGNIZED." The translator makes no attempt to translate this line but simply copies it to the output file.

Most of the common pseudo-ops are included in the translator's internal tables. If you get a syntax error for a pseudo-op or macro name which appears in your input source file you should then run the utility, ADNAME.COM as described below. This will prevent future occurrences of this error. As noted below, this utility does not translate or, more accurately, it results in a one-to-one translation (exact copy) of the entire line.

These translators do not support the TDL .DEFINE (MACRO) pseudo-op since there is not, in general, a unique translation. These can usually be handled after translation with an editor. The .EXIT (EXITM) pseudo-op is included, however.

All arithmetic and logical operators of the TDL set are supported with the exception of the unary radix change.

Three of the conditional assembly pseudo-ops of the TDL set are supported. These are: .IFN (IF) which is false if its argument evaluates to zero and true otherwise, .IFB (IF NUL) which is true if its argument is blank, and .IFNB (IF NOT NUL) which is true if its argument is not blank. The ELSE construct is also supported. No part of the body of the IF or ELSE is permitted on the same line as the IF statement itself. Left and right square brackets must surround the arguments of .IFB and

This utility permits the user to add custom macro names or pseudo-ops to the translator's internal tables. It will operate on either ITOT.COM or TTOI.COM. It will also operate on either of these files if they have been renamed. Please note that no translation occurs for these names. The use of ADNAME permits the translators to recognize these names and to copy the line from the input file to the output file without generating an error message. If you experience difficulty with assembly of a translated file it may be necessary to edit the translated file to correct for the particular pseudo-ops used by your assembler. The command line format for ADNAME is:

A > ADNAME filename

where 'filename' is ITOT, TTOI or whatever you may have renamed them. A filetype of COM is automatically assigned by ADNAME. The program will then prompt you for the new names to be entered. Each entry is terminated by a carriage return. A blank line (CR) terminates the program. The old file is renamed with the same filename and with a filetype of BAK. The new file is renamed with the same filename and with a filetype of COM. The new COM file will include your new names. If you wish you may erase the BAK file. We strongly recommend, however, that you always keep a backup copy of the original files. The space allocated in the translators for this function is 200 bytes. If N is the number of new names and C is the total number of characters in the new names then 2*N+C must be <= 200. Attempts to exceed this number will not be accepted and a warning message will be issued.

ADNAME may be used on the current COM file as often as you please. Any new names will be added to those already included and a new COM file and new BAK file will be created.

The Z-80 peculiar instructions for TDL differ from the extended 8080 set as used here. The extended 8080 mnemonic set is identical to that released by Digital Research as Z80.LIB to be used with their CP/M "MAC" Macro Assembler. The following conventions are used in the table.

r - any register or memory

rr - any register pair or stack pointer

nn - 8 bit immediate data (0 to 255)

d - 8 bit signed displacement (-128 to 127)

nnnn - 16 bit address or immediate data (0 to 65535)

b - bit number (0 to 7, 7 is most significant)

addr - 16 bit address within PC+127 through PC-128

In cases involving a displacement, d, this parameter is always the last one in operand field.
