The Pascal/VS compiler is a processing program which translates Pascal/VS source programs, diagnosing errors as it does so, into IBM System/370 machine instructions.

The compiler may be executed under the following operating system environments:

- OS/370 Batch (VS2 R3.7)
- Time Sharing Option (TSO) of OS/VS2

1.0 INTRODUCTION
This section applies only to those who are using Pascal/VS under the Conversational Monitor System (CMS) of Virtual Machine Facility/370 (VM/370). If you are not using CMS then you may skip this entire section.

For a description of the syntax notation used to describe commands, see "Command Syntax Notation" on page 117.

There are four steps to running a Pascal/VS program under CMS.

1. The program is compiled to produce an object module;
2. A load module is generated from the object module;
3. All files used within the program are defined using the FILEDEF command;
4. The load module is invoked.

---

Figure 1. The PASCALVS command of CMS:

```
PASCALVS fn [maclibs...] ([options...] PRINT NOPRINT CONSOLE NOOBJ) DISK
```

invokes the Pascal/VS compiler.

---

2.1 HOW TO COMPIL E A PROGRAM

2.1.1 Invoking the Compiler

The standard method of invoking the Pascal/VS compiler under CMS is by means of an EXEC called PASCALVS.

To compile a Pascal/VS program, the EXEC may be invoked in its simplest form by the command

```
PASCALVS fn
```

where "fn" is the file name of the program. The file type is always assumed to be "PASCAL".

The compiler translates a source program into object code, which it stores in a file. The name of this file is identical to the name of the source program. Its file type is "TEXT".

For example, to compile a program which resides in a file called "SORT PASCAL", the command would be:

```
PASCALVS SORT
```

If the compilation completes without errors, then the file named "SORT TEXT" will contain the resulting object code.

2.1.2 The PASCALVS Command

The generalized form of the PASCALVS command is illustrated in Figure 1. The operands of the command are defined as follows:

- **fn** is the file name of the source program; the assumed file type is "PASCAL".
- **maclibs...** are optional macro libraries required by the %INCLUDE facility. Up to eight may be specified.
- **options...** are compiler options, see "Compiler Options" on page 29.

The command options PRINT, NOPRINT, and DISK specify where the compiler listing is to be placed.

- **PRINT** specifies that the listing is to be spooled to the virtual printer. This is the default.
- **NOPRINT** specifies that the listing is to be suppressed. This option automatically forces the following three compiler options to become active:
  - NOSOURCE
  - NOXREF
  - NOLIST
- **DISK** specifies that the listing is to be stored as a file on your A disk. The file is named "fn LISTING", where "fn" is the file name of the source program.
- **CONSOLE** This command option specifies that the console messages produced by
the compiler are be stored as a file on your A disk. The name assigned to the file is "fn CONSOLE". If CONSOLE is not specified, then the messages will be displayed on the terminal console.

NOOBJ

This command option suppresses the production of an object module by disabling the code generation phase of the compiler. This option is useful when you are using the compiler only as an error diagnoster.

For an explanation of the possible error messages and return codes produced from the EXEC, see "Messages from PASCALVS exec" on page 113.

2.1.3 The %INCLUDE Maclibs

The macro libraries (maclibs) that may be specified when invoking the PASCALVS command are those required by the %INCLUDE facility. When the compiler encounters an %INCLUDE statement within your program it will search the maclibs (in the order in which they were specified in the PASCALVS command) for the member named. When found, the maclib member becomes the input stream for the compiler. After the compiler has read the entire member, it will continue reading in the previous input stream (immediately following the %INCLUDE statement).

The default maclib named PASCALVS need not be specified. It is always implicitly provided as the last maclib in the search order.

2.1.4 Passing Compiler Options

Compile time options (see "Compiler Options" on page 29) are parameters that are passed to the compiler which specify whether or not a particular feature is to be active. A list of compiler options may be specified in the PASCALVS parameter list. The options list must be preceded by a left parenthesis "(".

For instance, to compile the program "TEST PASCAL" with the debug feature enabled and without a cross reference table, you would invoke the following command:

```
PASCALVS TEST ( DEBUG NOXREF
```

2.1.5 The Compiler Listing

The compiler generates a listing of the source program with such information as the lexical nesting structure of the program and cross reference tables. For a detailed description of the information on the source listing see "Source Listings" on page 33.

2.1.6 Compiler Diagnostics

Any compiler-detected errors in your program will be displayed on your terminal console (or written to a disk file if the CONSOLE options is specified). The errors will also be indicated on your source listing at the lines where the errors were detected. The diagnostics are summarized at the end of the listing.

When an error is detected, the source line that was being scanned by the compiler is displayed on your console. Immediately underneath the printed line a dollar symbol ('$') is placed at each location where an error was detected. This symbol serves as a pointer to the approximate location where the error occurred within the source record.

Accompanying each error indicator is an error number. Beginning with the following line of your console a diagnostic message is produced for each error number.

For a synopsis of the compiler-generated messages see "Pascal/VS Compiler Messages" on page 95.
2.1.7 Sample compilation

Figure 2. Sample compilation under CMS
2.2 HOW TO BUILD A LOAD MODULE

The PASCMOD EXEC generates load modules from Pascal/VS object code. If your program consists of just one source module (that is, you have no segment modules), a load module can be generated by simply invoking PASCMOD with the name of the program. For example, if a program named SORT was successfully compiled (which implies that "SORT TEXT" exists), then a load module may be generated with:

PASCMOD SORT

The resulting module would be called "SORT MODULE". A load map is stored in "SORT MAP".

The general form of the PASCMOD command is shown in Figure 3.

The operands of the command are defined as follows:

- **main** is the name of the main program module.
- **names** are the names of segment modules and text libraries (TXTLIB's) which are to be included. If a name "n" is specified and there are two files named n TEXT and n TXTLIB, then the TEXT file will be included and the TXTLIB will be searched.
- **options** is a list of options. (see "Module Generation Options."

The resulting load module will be given the name "main MODULE A". The load map of the module will be stored in "main MAP A".

The Pascal/VS run time library resides in "PASCALVS TXTLIB"; PASCMOD implicitly appends this library to the list that you specify.

As an example, let us build a load module for a pre-compiled program which resides in three source modules: MAIN, ASEG, and BSEG. This program calls routines that reside in a txtlib called UTILITY. The following command would generate a load module called MAIN MODULE:

PASCMOD MAIN ASEG BSEG UTILITY

2.2.1 Module Generation Options

The following are recognized as options to the PASCMOD command.

- **DEBUG**
  This option links the debugging routines into the load module so that the interactive debugger can be used. (See "Debug - Pascal/VS Interactive Debugger" on page 53.)

- **NAME name**
  This option specifies an alternate name for the load module. The resulting load module and map will have the name "name MODULE A" and "name MAP A".

2.2.2 Run time Libraries

Routines which make up the Pascal/VS runtime environment reside in a text library called "PASCALVS TXTLIB". It must be present in order to resolve the linkages from the program being prepared for execution.

The name of the txtlib which contains the runtime Debug support is "PASDEBUG TXTLIB". (see "Debug - Pascal/VS Interactive Debugger" on page 53 for a description of Debug).
2.3 HOW TO DEFINE FILES

Before you invoke the generated load module, you must first define the files that your program requires. This is done with the FILEDEF command.

The first parameter of the FILEDEF command is the file's ddname. The ddname to be associated with a particular file variable in your program is normally the name of the file variable itself, truncated to eight characters.

For example, the ddnames for the variables declared within the Pascal declaration below would be SYSIN, SYSPRINT, and OUTPUTFILE, respectively.

```pascal
var
  SYSIN, SYSPRINT : TEXT;
  OUTPUTFILE : file of INTEGER;
```

The text file named OUTPUT receives the execution time error diagnostics. You must always define this file prior to executing any Pascal/VS program. This file is often assigned to the terminal.

The text file named INPUT is required by the interactive debugger ("Debug - Pascal/VS Interactive Debugger" on page 53) to be assigned to the terminal.

If a particular file is to be opened for input, attributes such as LRECL, BLKSIZE, and RECFM are obtained from the (presumably already existing file.

For the case of files to be opened for output, the LRECL, BLKSIZE, or RECFM will be assigned default values if not specified. For a description of the defaults see "Data Set DCB Attributes" on page 39.

The FILEDEF commands required for each of the three file variables in the example above and for INPUT and OUTPUT could be as shown in Figure 4.

2.4 HOW TO INVOKE THE LOAD MODULE

After the module has been created and the files defined, you are ready to execute the program. This is done by invoking the module.

If your program expects to read a parameter list via the PARMs function, the list must follow the module name:

```
modname [parms...]
```

where "modname" is the name of the load module and "parms" are the parameters (if any) being passed.

Run time options are also passed as a parameter list. To distinguish runtime parameters being passed to the Pascal/VS environment from those that your program will read (via the PARMs function), the runtime parameter list must be terminated with a slash "/". The program parameters, if any, must follow the "/".

```
modname [rtparms...] [parms...]
```

2.4.1 Run Time Options

The following options enable features in the Pascal/VS run time environment in which your program will be executing.

COUNT
This option causes instruction frequency information to be collected during program execution. This option will only have an effect if the program was both compiled and loaded with the DEBUG option.

DEBUG
The DEBUG option causes the interactive debugger, Debug ("Debug - Pascal/VS Interactive Debugger" on page 53) to gain initial control when you invoke your program. Note: this option is valid only if the load module was generated with the DEBUG option ("Module Generation Options" on page 6).
This section describes how to compile a Pascal/VS program under the Time Sharing Option (T50) of OS/VS2. If you are not using TSO to run the compiler, you may skip this section.

Refer to "Command Syntax Notation" on page 117 for a description of the syntax notation used to describe commands.

There are four steps to running a Pascal/VS program.

Figure 5. PASCALVS CLIST syntax.

3.1 HOW TO COMPILe A PROGRAM

3.1.1 Invoking the Compiler

The Pascal/VS compiler is invoked under TSO by means of a CLIST. A sample CLIST named PASCALVS is provided to compile a Pascal/VS program.

data-set-name specifies the name of the primary input data set in which contains the source program to be compiled. This can be either a fully qualified name (enclosed in single quotation marks) or a simple name (to which the user identification will be prefixed and the qualifier "PASCAL" will be suffixed). This must be the first operand specified.

compiler-options-list specifies one or more compiler options. See "Compiler Options" on page 29.

OBJECT(dsnamel specifies that the object module produced by the compiler is to be written to the data set named in the parentheses. This can be either a fully qualified name (enclosed within triple quotation marks ' ''...''') or a simple name (to which the identification qual-

1 Triple quotes are required because the CLIST processor removes the outer quotes within a keyword sub-operand list.
ifier will be prefixed and the qualifier "OBJ" suffixed).

NOOBJECT specifies that no object module is to be produced. The compiler will diagnose errors only.

If neither OBJ nor NOOBJ is specified then object module produced by the compiler will be written to a default data set. If the data set specified in the first operand contains a descriptive qualifier of "PASCAL", the CLIST will form a data set name for the object module by replacing the descriptor qualifier of the input data set with "OBJ". If the descriptive qualifier is not "PASCAL", then you will be prompted for the object module data set name.

If the first operand of PASCALVS specifies the member of a partitioned data set, the member name will be ignored - the generated data set name will be based on the name of the partitioned data set.

As an example, given that the user identification is ABC, the following commands will produce object modules with the name shown.

PASCALVS SORT  
object module: 'ABC.SORT.OBJ'

PASCALVS 'DEF.PDS.PASCAL(MAIN)'  
object module: 'DEF.PDS.OBJ'

PASCALVS 'ABC.PROG.PAS'  
user prompted for object module name

PRINT() specifies that the compiler listing is to be written at the terminal; no other copy will be available.

PRINT(dsnname) specifies that the compiler listing is to be written on the data set named in the parentheses. This can be either a fully qualified name (enclosed within triple quotation marks '"""') or a simple name (to which the identification qualifier will be prefixed and the qualifier "LIST" suffixed).

SYSPRINT(sysout-class) specifies that the compiler listing is to be written to the sysout class named in parentheses.

NOLIB(dsnname-list) specifies that the %INCLUDE facility is being utilized. Within the parentheses is a list of the names of one or more partitioned data sets that are to be searched for members to be included within the input stream.

If the list contains more than one name, the entire list must be enclosed within quotes. Any fully qualified name within the quoted list must be enclosed in double quotes '"""'.

See "Using the %INCLUDE Facility" on page 11.

Example 1

Operation: Invoke the Pascal/VS compiler to process a Pascal/VS program

Known: User-identification is ABC

Data set containing the program is named ABC.SORT.PASCAL

The compiler listing is to be directed to the printer.

Default options and data set names are to be used.

PASCALVS SORT SYSPRINT(A)

specifies that the compiler listing is not to be produced. This operand activates the following compiler options: NOSOURCE, NOXREF, NOLIST

CONSOLE() specifies that the compiler generated messages are to be displayed on the terminal console. This is the default.

CONSOLE(dsnname) specifies that the compiler generated messages are to be written to the data set named in the parentheses. This can be either a fully qualified name (enclosed within triple quotation marks '"""') or a simple name (to which the identification qualifier will be prefixed and the qualifier "CONSOLE" suffixed).

Triple quotes are required because the CLIST processor removes the outer quotes within a keyword sub-operand list.

10 Pascal/VS Programmer’s Guide
Example 2

Operation: Invoke the Pascal/VS compiler to process a Pascal/VS program

Known: User-identification is XYZ
Data set containing the program is named ABC.TEST.PASCAL
The compiler listing is to be directed to a data set named XYZ.TESTLIST.LIST.
The long version of the cross reference listing is preferred.
Default options and data set names are to be used for the rest.
PASCALVS 'ABC.TEST.PASCAL' + XREF(LONG),PRINT(TESTLIST)

3.1.2 Using the %INCLUDE Facility

If the %INCLUDE facility is used within the source program, then the names of the library or libraries to be searched must be listed within the LIB parameter of the PASCALVS CLIST.
The standard include library supplied by IBM is called "SYS1.PASCALVS.MACLIB"
This library must be specified in the LIB list if your program contains an %INCLUDE statement for one of the IBM supplied members.
When the compiler encounters an %INCLUDE statement within the source program, it will search the partitioned data set(s) in the order specified for the member named within the statement. When found, the member becomes the input stream for the compiler. After the compiler has read the entire member, it will continue reading from the previous input stream immediately following the %INCLUDE statement.

Example 1

Operation: Invoke the Pascal/VS compiler to process a Pascal/VS program which utilizes the %INCLUDE facility.
Known: User-identification is P123
Data set containing the program is named 'P123.MAIN.PASCAL'
The source to be included is stored in two partitioned data sets by the names of 'P123.PASLIB', 'SYS1.PASCALVS.MACLIB'.
Default options and data set names are to be used for the rest.
PASCALVS MAIN LIB('PASLIB,+' 'SYS1.PASCALVS.MACLIB')

3.1.3 Compiler Diagnostics

By default, compiler diagnostics are displayed on your terminal. If the CONSOLE(dsname) operand appears on the PASCALVS command, then the diagnostics will be stored in a data set. The errors will also be indicated on your source listing at the lines where the errors were detected. The diagnostics are summarized at the end of the listing.
When an error is detected, the source line that was being scanned by the compiler is printed on your terminal (or to the CONSOLE data set). Immediately underneath the printed line, a dollar symbol ('$') is placed at each location where an error was detected. This symbol serves as a pointer to indicate the approximate location where the error occurred within the source record.
Accompanying each error indicator is an error number. Beginning with the following line of your console a diagnostic message is produced for each error number.
For a synopsis of the compiler generated messages see "Pascal/VS Compiler Messages" on page 95.

3 The high-level qualifier name (SYS1) may be different at your installation.

Running a Program under TSO 11
3.2 HOW TO BUILD A LOAD MODULE

To generate a load module from a Pascal/VS object module, you may use either the TSO LINK command or a CLIST named "PASCMOD" (Figure 6 on page 13). The CLIST performs the same function as the LINK command except that it will automatically include the Pascal/VS runtime library in generating the load module. Also, if the debugger is to be utilized, the CLIST will include the Pascal/VS debug library. (A complete description of the LINK command is contained in the TSO Command Language Reference Manual.)

Every Pascal/VS object module contains references to the runtime support routines. These routines are stored in a library called "SYS1.PASCALVS.LOAD"

This library must be linked into a Pascal/VS object module in order to resolve all external references properly. If the PASCMOD CLIST is used, this library is included automatically.

If the interactive debugger is to be utilized, then the library containing the debug environment must be included in the linking. The name of this library is "SYS1.PASDEBUG.LOAD"

This library must appear ahead of the runtime library in search order. If the PASCMOD CLIST is used, this library will be included if the option DEBUG is specified.

If more than one object module is being linked together, then an entry point should be specified by means of a linkage editor control card. The name of the entry point for any Pascal/VS program is AMPXSTRT.

4 The high-level qualifier name (SYS1) may be different at your installation.

Figure 6. The TSO PASCMOD CLIST description.

data-set-name specifies the name of a data set containing a Pascal/VS object module and/or linkage editor control cards. If more than one object module is to be linked, then their names should appear in the OBJECT sub-parameter list.

You may substitute an asterisk (*) for the data set name to indicate that you will enter control statements from your terminal. The system will prompt you to enter the control statements. A null line indicates the end of your control statements.

OBJECT('dsname-list') specifies a list of data sets which contain object modules to be included in the link edit. Because of CLIST restrictions, the list must be enclosed in single quotes; fully qualified names within the list must be enclosed in double quotes ('"..."').

LIB('dsname-list') specifies one or more names of library data sets to be searched by the linkage editor to locate load modules referred to by the module being processed, that is, to resolve external references. The name of the Pascal/VS runtime library is implicitly appended to the end of this list; you need not specify it.

Because of CLIST restrictions, the list must be enclosed in single quotes; fully qualified names within the list must be enclosed in double quotes ('"..."').

DEBUG specifies that the Pascal/VS interactive debugger is to be utilized on the resultant load module. This will cause the Pascal/VS debug library to be included among the libraries to be searched to resolve external references.

All other operands of the PASCMOD CLIST are identical to their counterparts in the LINK command as described in the TSO Command Language Reference Manual.
Example

Operation: Create a load module from a compiled Pascal/VS program consisting of three object modules.

Known: User-identification is ABC.
Data sets containing the three object modules:

- ABC.SORT.OBJ
- ABC.SEG1.OBJ
- ABC.SEG2.OBJ

The resulting load module is to be stored as a member named SORT in a data set named ABC.PROGS.LOAD

(The user's input is in lower case; the system replies are high-lighted.)

```
pascmod * load(progs(sort)) +
   object('sort,seg1,seg2')
ENTER CONTROL CARDS
   entry ampstrt

READY
```
### 3.3 HOW TO DEFINE FILES

Before you invoke the generated load module, you must first define the files that your program requires. This is done with the ALLOC command.

The ddname to be associated with a particular file variable in your program is normally the name of the variable itself, truncated to eight characters.

For example, the ddnames for the variables declared within the Pascal declaration below would be SYSIN, SYSPRINT, and OUTPUTFILE, respectively.

```pascal
var
  SYSIN,
  SYSPRINT : TEXT;
  OUTPUTFILE : file of
               INTEGER;
```

The text file named OUTPUT receives the execution time error diagnostics. You must always allocate the ddname OUTPUT prior to executing any Pascal/VS program. This ddname is often assigned to the terminal.

The text file named INPUT is required by the interactive debugger (see "Debug - Pascal/VS Interactive Debugger" on page 53) to be assigned to the terminal.

For the case of files to be opened for output, the LRECL, BLKSIZE, or RECFM will be assigned default values if not specified via the ATTR command. For a description of the defaults see "Data Set DCB Attributes" on page 39.

The ALLOC commands required for each of the three file variables in the example above and for INPUT and OUTPUT could be as shown in Figure 7.

---

**Figure 7. Examples of TSO data set allocation commands**

```
ATTR F80 LRECL(80) BLKSIZE(80) RECFM(F)
ALLOC DDNAME(SYSIN) DSNAME(INPUT.DATA) SHR
ALLOC DDNAME(SYSPRINT) SYSPUT(A)
ALLOC DDNAME(OUTPUTFILE) DSNAME(OUTPUT.DATA) NEW SPACE(100) BLOCK(3120)
ALLOC DDNAME(OUTPUT) DSNAME(*) USING(F80)
ALLOC DDNAME(INPUT) DSNAME(*) USING(F80)
```
3.4 INVOKE THE LOAD MODULE

After the module has been created and the files defined, you are ready to execute the program. This is done by the CALL command (see Figure 8). The operands of the CALL command are as follows.

\[ \text{CALL dsname[(member)] [ '[options/] [parms]' ]} \]

**dsname(member)**
- Specifies the name of a partitioned data set and the member where the load module to be invoked is stored. If the member name is omitted, then the member "TEMPNAME" will be the load module invoked.
- `dsname` may be either a simple name (to which the user identification is prefixed and the qualifier "LOAD" is suffixed), or a fully qualified name in quotes.

**options**
- Specifies one or more run time options separated by either a comma or a blank. (See "Run Time Options").

**parms**
- Specifies a parameter string which is to be passed to the program. The parameter string is retrieved from within the program by the `PARMS` function.

The total length of the quoted string (options plus parms) must not exceed 100 characters.

### 3.4.1 Run Time Options

The following options enable features in the Pascal/VS run time environment in which your program will be executing.

**COUNT**
- This option causes instruction frequency information to be collected during program execution. This option will only have an effect if the program was compiled with the DEBUG option and linked with the Debug library.\(^5\)

**DEBUG**
- The DEBUG option causes the interactive debugger to gain initial control when you invoke your program. For a description of the debugger see "Debug - Pascal/VS Interactive Debugger" on page 53.

**Note**: this option is valid only if the load module was linked with the Debug library.\(^5\)

---

\(^5\) The Debug library will be included if the PASCMOD CLIST is invoked with DEBUG specified. See "How to Build a Load Module" on page 12.

3.5 SAMPLE TSO SESSION

```plaintext
READY
pascalvs lander sysprint(a) list

INVOKING PASCAL/VS R1.0
NO COMPILER DETECTED ERRORS
SOURCE LINES: 47; COMPILE TIME: 0.19 SECONDS; COMPILE RATE: 15032

READY
pascmod lander load(programs(lander))

alloc ddname(input) dsname(*)

alloc ddname(output) dsname(*)

call programs(lander) 'parms go here'
```

Figure 9. Sample TSO session of a compile, link-edit, and execution.

Figure 9 is an example of a TSO session which compiles an already existing source module, link edits it, and executes it. The commands entered from the terminal are in lower case; those produced by the system are in upper case and high-lighted.
This section describes how to compile and execute Pascal/VS programs in an OS Batch environment. If you are not using the compiler under OS Batch then you may skip this section.

4.1 JOB CONTROL LANGUAGE

Job control language (JCL) is the means by which you define your jobs and job steps to the operating system; it allows you to describe the work you want the operating system to do, and to specify the input/output facilities you require.

The JCL statements which are essential to run a Pascal/VS job are as follows:

- JOB statement, which identifies the start of the job.
- EXEC statement, which identifies a job step and, in particular, specifies the program to be executed, either directly or by means of a cataloged procedure (described subsequently).
- DD (data definition) statement, which defines the input/output facilities required by the program executed in the job step.
- /* (delimiter) statement, which separates data in the input stream from the job control statements that follow this data.

A full description of job control language is given in the publication OS/VS2 JCL (GC28-0692).

4.2 HOW TO COMPILE AND EXECUTE A PROGRAM

The job control statements shown in Figure 10 on page 20 are sufficient to compile and execute a Pascal/VS program consisting of one module. This program uses only the standard files INPUT and OUTPUT. For a more generalized description of input/output refer to "How to Access Data Sets" on page 27 and "Using Input/Output Facilities" on page 39. Any options to be passed to the compiler are placed within the OPTIONS parameter of the EXEC statement.
In the sample JCL, "EXAMPLE" is the name of the job. The job name identifies the job within the operating system; it is essential. The parameters required in the JOB statement depend on the conventions established for your installation.

The EXEC statement invokes the IBM supplied cataloged procedure named PASCG. When the operating system encounters this name, it replaces the EXEC statement with a set of JCL statements that have been written previously and cataloged in a system library. The cataloged procedure contains three steps:

PASC The first pass of the compiler processes the Pascal/VS program and translates it into an intermediate form that will serve as input for the next step.

PASCT The second pass of the compiler reads in the intermediate code produced from the first pass and produces an object module.

GO The LOADER is invoked to process the object module by loading it into memory and including the appropriate runtime library routines. The resulting executable program is immediately executed.

The DD statement named "PASC.SVSIN" indicates that the program to be processed in procedure step PASC follows immediately in the card deck. "SYsin" is the name that the compiler uses to refer to the data set or device on which it expects to find the program.

The delimiter statement /* indicates the end of the data.

The DD statement named "GO.INPUT" indicates that the data to be processed by the program (in procedure step GO) follows immediately in the card deck.

4.3 CATALOGED PROCEEDURES

Regularly used sets of job control statements can be prepared once, given a name, stored in a system library, and the name entered in the catalog for that library. Such a set of statements is termed a cataloged procedure. A cataloged procedure comprises one or more job steps (though it is not a job, because it must not contain a JOB statement). It is included in a job by specifying its name in an EXEC statement instead of the name of a program.

Several IBM-supplied cataloged procedures are available for use with the Pascal/VS compiler. It is primarily by means of these procedures that a Pascal/VS job will be run.

The use of cataloged procedures saves time and reduces errors in coding frequently used sets of job control statements. If the statements in a cataloged procedure do not match your requirements exactly, you can easily modify them or add new statements for the duration of a job.

It is recommended that each installation review these procedures and modify them to obtain the most efficient use of the facilities available and to allow for installation conventions.
4.4 IBM SUPPLIED CATALOGED PROCEDURES

The standard cataloged procedures supplied for use with the Pascal/VS compiler are:

- PASCC Compile only
- PASCCG Compile, load-and-execute
- PASCCl Compile and link edit
- PASCClG Compile, link edit, and execute

These cataloged procedures do not include a DD statement for the source program; you must always provide one. The DDname of the input data set (SYSIN); the procedure step name which reads the input data set is PASC. For example, the JCL statements that you might use to compile, link edit, and execute a Pascal/VS program is as follows:

```plaintext
//JOBNAME JOB
//STEP1 EXEC PASCClG
//PASC.SYSIN DD *

(insert Pascal/VS program here to be compiled)
```

The listings and diagnostics produced by the compiler are directed to the device or data set associated with the DDname SYSPRINT. Each cataloged procedure routes DDname SYSPRINT to the output class where the system messages are produced (SYSOUT=).

The object module produced from a compilation is normally placed in a temporary data set and erased at the end of the job. If you wish to save it in a cataloged data set or punch it to cards then the DDname SYSPUNCH in procedure step PASCT must be overridden. For example, to compile a program stored in data set "T123SORT.PASCAl" and to store the resulting object module in a data set named "T123SORT.OBJ" the following JCL might be employed:

```plaintext
//JOBNAME JOB
//STEP1 EXEC PASCC
//PASC.SYSIN DD DSN=T123SORT.PASCAl, DISP=SHR
//PASC.T.SYSPUNCH DD DSN=T123SORT.OBJ, UNIT=TSOPACK,
// DISP=(NEW,CATLG)
```
4.4.1 **Compile Only (PASCC)**

This cataloged procedure (Figure 11) compiles one Pascal/VS source module and produces an object module. It consists of two steps, PASC and PASCT, which are common to all of the cataloged procedures described in this chapter.

Step PASC reads in the source module, diagnoses errors, produces a listing, and translates the source into an intermediate form which it passes to the PASCT step. The PASCT step produces the object module and writes it to the data set associated with DDname SYSPSUNCH.

The DD statement for the object module defines a temporary data set named &&LOADSET. The term MOD is specified in the DISP parameter and as a result, if the procedure PASCC is invoked several times in succession for different source modules, &&LOADSET will contain a concatenation of object modules. The linkage editor and loader will accept such a data set as input.
4.4.2 Compile, Load, and Execute (PASCCG)

In this cataloged procedure (Figure 12), the first two steps compile a Pascal/VS source module to produce an object module. In the third step (named GO), the loader is executed; this program processes the object module produced by the compiler and executes the resultant executable program immediately.

The DD statement labeled SYSLIB in step GO describes the libraries from which external references are to be resolved. If you have a library of your own from which you would like external references to be resolved, then pass its name in the LKLBDNS operand.

Object modules from previous compilations may also be included in the loader's input stream by concatenating them in the SYSLIN DD statement.

As an example, a program in a data set named "DOE.SEARCH.PASCAL" needs to be compiled and then loaded with an object module named "DOE.SORT.OBJ". In addition, several external routines are called from within the program which reside in a library named "DOE.MISC.OBJLIB". The following JCL statements would compile the program and execute it.

```
//DOE JOB
//STEP1 EXEC PASCCG,
// LKLBDNS='DOE.MISC.OBJLIB'
//PASC.SYSIN DD DSN=DOE.SEARCH.PASCAL,
// DISP=SHR
//GO.SYSLIN DD
// DD DSN=DOE.SORT.OBJ,
// DISP=SHR
```
4.4.3 Compile and Link Edit (PASCCL)

In this cataloged procedure (Figure 13), a Pascal/VS source module is compiled to produce an object module and then the linkage editor is executed to produce a load module.

The linkage editor step is named LKED. The DD statement with the name SYSLIB within this step specifies the library, or libraries, from which the linkage editor will obtain appropriate modules for inclusion in the load module. The linkage editor always places the load modules it creates in the standard data set defined by the DD statement with the name SYSLMOD. This statement in the cataloged procedure specifies a new temporary library &&GOSET, in which the load module will be placed and given the member name GO.

Multiple invocations of the PASCC cataloged procedure concatenates object modules. This permits several modules to be compiled and link edited conveniently in one job. The JCL shown in Figure 14 on page 25 compiles three source modules and then link edits them to produce a single load module. Within the example, each source module is a member of a partitioned data set named "DOE.PASCAL.SRCLIB1."

The member names are MAIN, SEG1, and SEG2. The resulting load module is to be placed in a preallocated library named "DOE.PROGRAMS.LOAD" as a member named MAIN.
Figure 14. Sample JCL to perform multiple compiles and a link edit.
4.4.4 Compile, Link Edit, and Execute (PASCCLG)

This cataloged procedure (Figure 15) performs a compilation, invokes the linkage editor to form a load module from the resulting object module, then the load module is executed.

The first three steps of this procedure are identical to those of the PASCCL procedure. An additional fourth step (named GO) executes your program.
4.5 HOW TO ACCESS AN %INCLUDE LIBRARY

The DD statement named SYSLIB in procedure step PASC defines the libraries from which included source is to be retrieved.

When the compiler encounters an %INCLUDE statement within the source module, it will search the library or libraries specified by SYSLIB for the member named in the statement. When found, the library member becomes the input stream for the compiler. After the compiler has read the entire member, it will continue where it left off in the previous input stream.

You may specify an %INCLUDE library by means of the INCLLIB parameter of the cataloged procedures, or by overriding the SYSLIB DD statement by specifying a DD statement with the name PASC.SYSLIB.

Example

```c
//JOBNAME JOB
// EXEC PASC CG
//PASC.SYSLIB DD DSN=...,DISP=SHR
//PASC.SYSIN DD *
/*
```

4.6 HOW TO ACCESS DATA SETS

Every file variable operated upon in your program must have an associated DD statement for the GO step which executes your program. The DDname to be associated with a particular file variable in your program is normally the name of the variable itself, truncated to eight characters.

For example, the DDnames for the variables declared within the Pascal declaration below would be SYSIN, SYSPRINT, and OUTPUTFI, respectively.

```c
var
SYSIN,
SYSPRINT: TEXT;
OUTPUTFILE: file of INTEGER;
```

The files named OUTPUT and INPUT need not be explicitly defined by you if you use the cataloged procedures. Both cataloged procedures which execute a Pascal/VS program (PASC CG and PASCCLG) contain DD statements for OUTPUT and INPUT. OUTPUT is assigned to the output class where the system messages and compiler listings are produced (SYSOUT=*). INPUT is defined as a dummy data set.

If the Pascal/VS input/output manager attempts to open a data set which has an incomplete data control block (DCB), it will assign default values to the DCB as described in "Data Set DCB Attributes" on page 39. If you prefer not to rely on the defaults, then the LRECL, BLKSIZE, and RECFM should be explicitly specified in the DCB operand of the associated DD statement for a newly created data set (that is, one whose DISP operand is set to NEW).
4.7 EXAMPLE OF A BATCH JOB

//JOBNAME JOB
//STEP1 EXEC PASCC,OPTIONS='NOXREF'
//PASC.SYSIN DD *
program COPYFILE;
type
  F80 = file of
      packed array[1..80] of CHAR;
var
  INFILE, OUTFILE: F80;
procedure COPY(var FIN,FOUT: F80);
  external;
begin
  RESET(INFILE);
  REWRITE(OUTFILE);
  COPY(INFILE,OUTFILE);
end.
/*
//STEP2 EXEC PASCCLG,OPTIONS='NOXREF'
//PASC.SYSIN DD *
segment IO;
type
  F80 = file of
      packed array[1..80] of CHAR;
procedure COPY(var FIN,FOUT: F80);
  entry;
begin
  while not EOF(FIN) do
    begin
      FOUT := FIN;
      PUT(FOUT);
      GET(FIN)
    end
end.;
/*
//LKED.SYSIN DD *
ENTRY COPYFILE
/*/n
//GO.INFILE DD *
  (data to be copied into data set goes here)

/*
//GO.OUTFILE DD DSN=P656706.TEMP.DATA,UNIT=TSOUSER,
//  DISP=(NEW,CATLG),
//  DCB=(RECFM=FB,LRECL=80,BLksz=3120),
//  SPACE=(3120,(1,1))
Figure 16. Example of a batch job

28 Pascal/VS Programmer's Guide
Compile time options indicate what features are to be enabled or disabled when the compiler is invoked. The following table lists all compiler options with their abbreviated forms and their default values.

5.1 CHECK/NOCHECK

If the CHECK option is enabled, the {Pascal/VS} compiler will generate inline code to perform runtime error checking. The %CHECK feature can be used to enable or disable particular checking code at specific locations within the source program. If NOCHECK is specified, all runtime checking will be suppressed and all %CHECK statements will be ignored. The runtime errors which may be checked are listed as follows:

CASE statements
Any case statement that does not contain an otherwise clause is checked to make sure that the selector expression has a value equal to one of the case label values.

Function routines
A call to a function routine is checked to verify that the called function returns a value.

Pointers
A reference to an object which is based upon a pointer variable is checked to make sure that the pointer does not have the value nil.

Subrange scalars
Variables which are declared as subrange scalars are tested when they are assigned a value to guarantee that the value lies within the declared bounds of the variable. This checking may occur when either the variable appears on the left side of an assignment statement or immediately after a routine call in which the variable was passed as a var parameter.

5.0 COMPILER OPTIONS

5.1 CHECK/NOCHECK

If the CHECK option is enabled, the {Pascal/VS} compiler will generate inline code to perform runtime error checking. The %CHECK feature can be used to enable or disable particular checking code at specific locations within the source program. If NOCHECK is specified, all runtime checking will be suppressed and all %CHECK statements will be ignored. The runtime errors which may be checked are listed as follows:

CASE statements
Any case statement that does not contain an otherwise clause is checked to make sure that the selector expression has a value equal to one of the case label values.

Function routines
A call to a function routine is checked to verify that the called function returns a value.

Pointers
A reference to an object which is based upon a pointer variable is checked to make sure that the pointer does not have the value nil.

Subrange scalars
Variables which are declared as subrange scalars are tested when they are assigned a value to guarantee that the value lies within the declared bounds of the variable. This checking may occur when either the variable appears on the left side of an assignment statement or immediately after a routine call in which the variable was passed as a var parameter.

For the sake of efficiency, the compiler may suppress checking when it is able to determine that it is semantically unnecessary. For example, the compiler will not generate code to check the first three assignment statements below; however, the last three will be checked.

```pascal
var
A : -10..10;
B : 0..20;
...
A := B - 10; (*no check*)
B := ABS(A); (*no check*)
A := B DIV 2; (*no check*)
...
A := B; (*check*)
B := AM10; (*check*)
A := -B; (*check*)
```

The compiler makes no explicit attempt to diagnose the use of uninitialized variables.

Subscript ranges
Subscript expressions within arrays or spaces are tested to guarantee that their values lie within the declared array or space bounds. As in the case of subrange checks, the compiler will suppress checks that are semantically unnecessary.

When a runtime checking error occurs, a diagnostic message will be sent to the file OUTPUT followed by a traceback of the routines which were active when the error occurred. See "Reading a Pascal/VS Trace Back" on page 49 for an example of a traceback due to a checking error.

Compiler Options 29
5.2 DEBUG/NODEBUG

An interactive debugging facility is available to debug Pascal/VS programs. The debugger is described in "Debug - Pascal/VS Interactive Debugger" on page 53. If the option DEBUG is enabled, the compiler will produce the necessary information that Debug needs in order to operate.

The DEBUG option also implies that the GOSTMT option is active.

NODEBUG indicates that Debug cannot be used for this segment.

5.3 GOSTMT/NOGOSTMT

The GOSTMT option enables the inclusion of a statement table within the object code. The entries within this table allow the run-time environment to identify the source statement causing an execution error. This statement table also permits the interactive debugger to place breakpoints based on source statement numbers. For a description of the debugger see "Debug - Pascal/VS Interactive Debugger" on page 53.

The inclusion of the statement table does not affect the execution speed of the compiled program.

NOGOSTMT will prevent the statement table from being generated.

5.4 LIST/NOLIST

The LIST/NOLIST option controls the generation or suppression of the translator pseudo-assembler listing (see "Assembly Listing" on page 37).

Note: The NOLIST option will cause any %LIST statement within the source program to be ignored.

5.5 MARGINS(m,n)

The MARGINS(m,n) option sets the left and right margin of your program. The compiler scans each line of your program starting at column m and ending at column n. Any data outside these margin limits is ignored. The maximum right margin allowed is 80.

The specified margins must not overlap the sequence field. A specification of MARGINS(1,80) implies that the source contains no sequence numbers.6

The default is MARGINS(1,72).

Note: When the PASCALVS clist is being invoked under TSO, the subparameters of the MARGINS option must be enclosed in quotes. For example,

MARGINS('1,72')

5.6 OPTIMIZE/NOOPTIMIZE

The OPTIMIZE option indicates that the compiler is to generate optimized code. NOOPTIMIZE indicates that the compiler is not to optimize.

5.7 SEQ(m,n)/NOSEQ

The SEQ(m,n) option specifies which columns within the program being compiled are reserved for a sequence field. The starting column of the sequence field is m; the last column of the field is n.

The compiler does not process sequence fields; but serve only to identify lines in the source listing. If the sequence field is blank, the compiler will insert a line number in the corresponding area in the source listing.

NOSEQ indicates that there is to be no sequence field.

The default is SEQ(73,80).

NOTES:
- The sequence field must not overlap the source margins.
- When the PASCALVS clist is being invoked under TSO, the subparameters of the SEQ option must be enclosed in quotes. For example, SEQ('73,80')

5.8 SOURCE/NOSOURCE

The SOURCE/NOSOURCE option controls the generation or suppression of the compiler source listing.

Note: The NOSOURCE option will cause any %PRINT statement within the source program to be ignored.

6 The option NOSEQUENCE has the same effect.
5.9 WARNING/NOWARNING

This option controls the generation or suppression of warning messages. The NOWARNING specification will suppress warning messages from the compiler.

5.10 XREF/NOXREF

The XREF/NOXREF option controls the generation or suppression of the cross-reference portion of the source listing. (See "Cross-reference Listing" on page 35).

Either a short or long cross-reference listing can be generated. A long cross-reference listing contains all identifiers declared in the program. A short listing consists of only those identifiers which were referenced.

To specify a particular listing mode, either the word LONG or SHORT is placed after the XREF specification and enclosed within parentheses. If no such specification exists, SHORT is assumed. For example, the specification

XREF(LONG)

would cause a long cross-reference table to be generated.

Note: If the PASCALVS clist is being invoked under TSO, a subparameter (SHORT or LONG) must be specified with the XREF option; there are no defaults.
6.0  HOW TO READ PASCAL/VS LISTINGS

6.1  SOURCE LISTINGS

The source listing contains information about the source program including nesting information of blocks and cross reference information.

6.1.1  Page Headers

The first line of every page contains the title, if one exists. The title is set with the $TITLE statement and may be reset whenever necessary. If no title has been specified, then the line will be blank.

The second line begins with "PASCAL/VS RELEASE x". This line lists information in the following order.

1. The PROGRAM/SEGMENT name is given before a colon. This name becomes the name of the control section (CSECT) in which the generated object code will reside.
2. Following the colon may be the name of the procedure/function definition which was being compiled when the page boundary occurred.
3. The time and date of the compile.
4. The page number.

The third line contains column headings. If the source being compiled came from a library (i.e., INCLUDE), then the last line of the heading identifies the library and member.

6.1.2 Nesting Information

The left margin contains nesting information about the program. The depth of nesting is represented by a number. The heading over this margin is:

S P B C I W STMT

S - a '1' in this column indicates that the line contains a comment which 'S'pans across the line.

P - indicates the depth of 'P'rocedure nesting.

B - indicates the depth of 'B'EGIN block nesting.

C - indicates the nesting of 'C'onditional statements. Conditional statements are if and case.

I - indicates the nesting of 'I'terative statements. Iterative statements are for, repeat and while.

W - indicates the nesting of 'W'ITH statements.

STMT is the heading of a column that numbers the executable statements of each routine. If the source line originated from an INCLUDE file, the include number and a colon (':') precede the statement number.

6.1.3 Statement Numbering

Pascal/VS numbers each executable statement according to the following rules:

- Every assignment, if, for, while, case, with, procedure call, and assert statement is given a number.
- The until part of a repeat statement is given a number.

A begin/end statement is not numbered because it serves only as a bracket for a sequence of statements and has no executable code associated with it. The statement numbers are given for runtime errors and to specify breakpoints in the interactive debugger (see "Debug - Pascal/VS Interactive Debugger" on page 53).

6.1.4 Page Cross Reference

The right margin contains an indicator for each identifier that appears in the associated line. The indicators have the following meanings:

- A number indicates a page number on which the corresponding identifier was declared.
- A '*' indicates that the corresponding identifier is being declared.
- A 'p' indicates that the corresponding identifier is predefined.
- A 'r' indicates that the corresponding identifier is a reserved keyword.
- A '?' indicates that the corresponding identifier is either undeclared, or will be declared further on in the program. This latter occurrence arises often in pointer type definitions.

6.1.5 Error Summary

Toward the end of the listing is the error summary. It contains the diagnostic messages corresponding to the compilation errors detected in the program.

6.1.6 Option List

The option list summarizes the options that were enabled for the compilation.

6.1.7 Compilation Statistics

The compiler prints summary statistics which tell the number of lines compiled, the time required, and compilation rate in lines per minute of (virtual) CPU time. These statistics are divided between two phases of the compiler: the syntax/semantic phase and the code generation phase. Also printed is the total time and accumulative rate for the sum of the phases.

Figure 18. Sample cross-reference listing

The cross reference listing lists alphabetically every identifier used in the program giving its attributes and both the page number and the source line number of each reference.

If the %INCLUDE facility was used, the cross reference listing will begin by listing all of the include-members by name with a reference number.

Each reference specification is of the following form:

\[ p/ [i:] 1 \]

where \( p \) is the page number on which the reference occurred; \( i \) is the number of the include-member if the reference took place within the member; \( 1 \) is the line number within the program or include-member at which the reference occurred.

The reference immediately following the identifier is the place in the source program where the identifier was declared.

The attribute specifications have the following meaning.

**IN name**

If the identifier is a record field, then this attribute specifies the name of the record in which the identifier was declared; otherwise, it specifies the name of the routine in which the identifier was declared.

**CLASS = class**

This attribute gives the class of the identifier:

- CONSTANT declared constant
- CONST PARAMETER
pass-by-const parameter

DEF VAR external def variable

ENTRY FUNCTION function routine declared as an ENTRY point

ENTRY PROCEDURE procedure routine declared as an ENTRY point

EXTERNAL FUNCTION external function routine

EXTERNAL PROCEDURE external procedure routine

FIELD record field

FORMAL FUNCTION function passed as a parameter

FORMAL PROCEDURE procedure passed as a parameter

FORTRAN FUNCTION external FORTRAN function

FORTRAN SUBROUTINE external FORTRAN subroutine

FUNCTION a user-defined or standard function

LABEL statement label

LOCAL VAR automatic variable

PROCEDURE a user-defined or standard procedure

REF VAR external ref variable

STATIC VAR static variable

TYPE type identifier

VAR PARAMETER pass-by-var parameter

UNDECLARED undeclared identifier

TYPE = type

This attribute gives the type of the identifier:

ARRAY an array type

BOOLEAN boolean type

CHAR character

FILE a file type

INTEGER fixed point numeric

POINTER a pointer type

REAL floating point numeric

RECORD a record type

SCALAR enumerated scalar or subrange

SET a set type

SPACE a space type

STRING a string type

OFFSET = n

This attribute specifies the byte offset (in decimal) within the dynamic storage area (DSA) of an automatic variable or parameter; the displacement of a record field within the associated record; or, the offset in the static area of a static variable.

LENGTH = n

This attribute specifies the byte length of a variable or the storage required for an instance of a type.

VALUE = n

This attribute specifies the ordinal value of an integer or enumerated scalar constant.
The compiler produces a pseudo assembly listing of your program if you specify the LIST option. The information provided in this listing include:

- **LOC**: Location relative to the beginning of the module in bytes (hexadecimal).
- **OBJECT CODE**: Up to 6 bytes per line of the generated text. If the line refers to a symbol or literal not yet encountered in the listing (forward reference) the base displacement format of the instruction is shown as four asterisks ('****').
- **STMT**: Basic assembly language description of generated instruction.
- **PSEUDO ASSEMBLY**: Annotation intermixed with the assembly instructions is the source line from which the instructions were generated. The source lines appear as comments in the listing.

---

**Figure 19. Sample assembly listing**
### 6.4 EXTERNAL SYMBOL DICTIONARY

The External Symbol Dictionary (ESD) provides one entry for each name in the generated program that is an external. This information is required by the linker/loader to resolve inter-module linkages. The information in this table is:

- **NAME** the name of the symbol.
- **TYPE** the classification of the symbol:
  - SD - Symbol Definition
  - LD - Local Definition
  - ER - External Reference
  - CM - Common
  - PC - Private Code.
- **ID** is the number provided to the loader in order to relocate address constants correctly.
- **ADDR** is the offset in the CSECT for an LD entry.
- **LENGTH** the size in bytes of the SD or CM entry.

The SD classification corresponds to the name of the module; the LD classifications are entry routines; ER names are external routines; CM names correspond to def variables. The private code section is where static variables are located.

### 6.5 INSTRUCTION STATISTICS

If Pascal/VS is requested to produce an assembly listing, it will also summarize the usage of 370 instructions generated by the compiler. The table is sorted by frequency of occurrence.
7.1 I/O IMPLEMENTATION

Pascal/VS employs OS access methods to implement its input/output facilities. Pascal/VS file variables are associated with a data set by means of a ddname. The Queued Sequential Access Method (QSAM) is used for sequential data sets. The Basic Partitioned Access Method (BPAM) is used for partitioned data sets (MACLIBs in CMS terminology).

7.2 DDNAME ASSOCIATION

For any identifier declared as a file variable the first eight characters of the identifier's name serves as the DDNAME of the file. As a consequence, the first eight characters of all file variables declared within a module should be unique. You must also be careful not to allow one of the first eight characters to be an underscore ('_') since this is not a valid character to appear in a DDNAME.

If you prefer, you may associate an arbitrary ddname with a file variable by explicitly specifying a ddname within the OPEN procedure (see "The OPEN Procedure" on page 46).

7.3 DATA SET DCB ATTRIBUTES

At runtime, associated with every Pascal/VS file variable is a Data Control Block (DCB) which contains information describing specific attributes of the associated data set. Among these attributes are

- the logical record length (LRECL);
- the physical block size (BLKSIZE);
- the record format (RECFM).

Pascal/VS supports only the following record formats:

F, FA, FB, FBA, V, VA, VB, VBA

Newly allocated (empty) data sets, that is, data sets intended for output might not have these attributes assigned. As far as Pascal/VS is concerned, there are two ways to specify the DCB attributes for such data sets:

- by being specified in the associated DDNAME definition (in CMS: the FILEDEF command; in TSO: the

7.4 TEXT FILES

Text files contain character data grouped into logical records. From a Pascal/VS language viewpoint, the logical records are lines of characters. Pascal/VS supports both fixed length and variable length record formats for text files. Characters are stored in their EBCDIC representations.

The predefined type TEXT is used to declare a text file variable in
Pascal/VS. The pointer associated with each file variable points to positions within a physical I/O buffer.

7.4.1 Opening a Text File

A closed file is opened automatically by the procedures GET and READ for input, and WRITE for output. To open a file explicitly, the procedures RESET, REWRITE, INTERACTIVE, and OPEN are provided.

The procedures RESET and INTERACTIVE are used to open a file for input. RESET allocates a buffer, reads the first logical record of the file into the buffer, and positions the file pointer at the beginning of the buffer. Therefore, given a text file F, the execution of the statement 'RESET(F)' would imply that 'F->' would reference the first character of the file. If a RESET operation is performed on an open file, the file is closed and then reopened.

Since RESET performs an implicit read operation to fill a file buffer, it is not well suited for files intended to be associated with interactive input. To alleviate this problem you should use the INTERACTIVE procedure to open the file. No initial read operation is performed on files opened in this manner. The file pointer has the value NIL until the first file operation is performed (namely GET or READ).

The PUT procedure, when applied to an output text file, causes the file pointer to be incremented by one character position. If, prior to the call, the number of characters in the current logical record is equal to the file's logical record length (LRECL), the file pointer will be positioned within the associated buffer to begin a new logical record.

When the file buffer is filled to capacity, the buffer is written to the associated physical file. The file pointer is then positioned to the beginning of the buffer so that it may be refilled on subsequent calls to PUT. The capacity of the buffer is equal to the file's physical block size (BLKSIZE).

To terminate a logical record before it is full requires a call to WRITELN (see "The WRITELN Procedure" on page 44).

7 The procedure PUT does not perform an implicit open on a file. Prior to a PUT operation, the associated output buffer must contain the data to be written. If the file is not open when the PUT operation is attempted, then no output buffer exists. (The file pointer will have the value NIL.)
7.4.3 Text File GET

The GET procedure, when applied to an input text file, causes the file pointer to be incremented by one character position. If the file pointer is positioned at the last position of a logical record, the GET operation will cause the end-of-line condition to become true (see "End of Line Condition") and the file pointer will be positioned to a blank. If, prior to the call, the end-of-line condition is true, then the file pointer will be positioned to the beginning of the next logical record.

If GET is called when the file pointer is positioned at the last character position of the file, the end-of-file condition becomes true. (See "End of File Condition" on page 42).

```
program EXAMPLE;
var
  INFILE : TEXT;
  C1,C2 : CHAR;
begin
  (*get first char of file*)
  RESET(INFILE);
  C1 := INFILE->;
  (*get second char of file*)
  GET(INFILE);
  C2 := INFILE->;
end.
```

Figure 25. Using GET on a TEXT file

7.4.4 The PAGE Procedure

The PAGE procedure causes a page eject to occur on a text output file which is to be associated with a printer (or to a disk file which will eventually be printed).

```
program EXAMPLE;
var
  PRINT: TEXT;
begin
  (*start new page*)
  PAGE(PRINT);
end.
```

Figure 26. Using the PAGE procedure

7.4.5 End of Line Condition

The end-of-line condition occurs on a text file opened for input when the file pointer is positioned after the end of a logical record. To test for this condition, the EOLN function is used.

The end-of-line condition becomes true when GET is executed for a file positioned at the last character of a logical record, or if a call to READ consumes all of the characters of the current logical record.

The file pointer will always point to a blank character (in EBCDIC, hexadecimal 40) when the end-of-line condition occurs.

The EOLN function is only applicable to text files.

```
program EXAMPLE;
var
  SYSIN: TEXT;
  CNT : 0..32767;
begin
  (* compute length of first logical record of SYSIN *)
  RESET(SYSIN);
  CNT := 0;
  while not EOLN(SYSIN) do begin
    CNT := CNT + 1;
    GET(SYSIN);
  end;
  WRITELN(CNT)
end.
```

Figure 27. Using the EOLN function
### 7.4.6 End of File Condition

The end-of-file condition becomes true when GET is executed for a file positioned at the last character of the last logical record, or if a call to READ consumes all of the characters of the last logical record.

The file pointer will always point to a blank character (hexadecimal 40) when the end-of-file condition occurs. To test for this condition, the EOF function is used.

Any calls to GET or READ for a file for which the end-of-file condition is true will be ignored.

```pascal
program EXAMPLE;
var
  SYSIH: TEXT;
  CHT : 0..32767;
begin
  (* compute number of logical records in file SYSIH *)
  RESET(SYSIH);
  CNT := 0;
  while not EOF(SYSIH) do begin
    CNT := CNT + 1;
    READLH(SYSIH)
  end;
  Writeln(CHT)
end.
```

Figure 28. Using the EOF function on a TEXT file

### 7.4.7 Text File READ

The READ procedure fetches data from a text file beginning at the current position of the file pointer. If the file pointer is not yet set, an initial GET operation is performed. This case occurs when a file is opened INTERACTIVELY.

If READ is called for a closed file, the file is opened for input by an implicit call to RESET.

When reading INTEGER or REAL data via the READ procedure, and no length field

is specified, all blanks preceding the data are skipped. In addition, logical record boundaries will be skipped. If the end-of-file condition should occur before a nonblank character is detected, the integer value 0 or the real value 0.0 will be returned.

Integer data begins with an optional sign ('+' or '-') followed by all digits up to, but not including, the first non-digit or up to the end of the logical record.

For example, given an input file positioned at the beginning of a logical record with the following contents:

```
95123SAN JOSE,CA
```

an integer read operation would bring in the value 95123. After the read, the file pointer would be positioned to the first 'S' character.

Real data begins with an optional sign ('+' or '-') and includes all of the following nonblank characters until one is detected that does not conform to the syntax of a real number.

For example, given an input file positioned at the beginning of a logical record with the following contents:

```
3.14159/2
```

a floating point read operation would bring in the floating point value 3.14159. After the read, the file pointer would be positioned to the '/' character.

The length field is the expression indicated in the following sample statement:

```
READ(file, variable : length_field);
```

If a length field value is specified, as many characters as are indicated by the value will be consumed by the read operation. The variable will be assigned from the beginning of the field. If the field is not exhausted after the variable has been assigned the data, the rest of the field will be skipped.
program EXAMPLE;
var
  ZIP, MAN : INTEGER;
  BALANCE: REAL;
begin
  READ(ZIP:5, MAN:6, BALANCE:9);
  WRITELN('ZIP = ', ZIP);
  WRITELN('MAN = ', MAN);
  WRITELN('BALANCE = ', BALANCE:8:2);
end.

Given the following input stream from file INPUT:
951239999991000.00JUNK
This program produces the following on file OUTPUT:
ZIP = 95123
MAN = 999999
BALANCE = 1000.00

Immediately after the READ statement was executed, file INPUT was positioned to the 'N' character.

Figure 29. Using READ with length qualifiers.

When reading data into variables declared as packed array of CHAR or STRING, data is read until one of the following three conditions occurs:

- the variable is filled to its declared capacity;
- an end-of-line condition is detected;
- the length field (if specified) is exhausted.

The length of a STRING variable will be set to the number of characters read. A variable declared as packed array of CHAR will be padded if necessary with blanks up to its declared length.

program DOREAD;
var
  INFILE : TEXT;
  R : array[1..10] of record
    NAME: STRING(25);
    AGE : 0..99;
    WEIGHT: REAL
  end;
begin
  INFILE := OPEN(INFILE, 'R', INTERACTIVE);
  for I := 1 to 10 do with R[I] do
    READ(INFILE, NAME, AGE);
    READ(INFILE, WEIGHT);
    READLN(INFILE);
end;

Figure 30. Using READ on TEXT files.

7.4.8 The READLN Procedure

The READLN procedure is applicable only to text files. It causes the characters between the file pointer position and the end of the logical record to be skipped.

In the case of text files opened with the INTERACTIVE attribute, the file pointer is positioned after the end of the logical record and the end-of-line condition is set to true. For non-INTERACTIVE files, the file pointer is positioned at the beginning of the next logical record (unless, of course, the end-of-file condition occurs).

If the end-of-line condition is true for an INTERACTIVE file prior to a call to READLN and the condition was not the result of a previous call to READLN, then the call is ignored. Two calls to READLN in succession will cause the following logical record to be skipped in its entirety.

If READLN is called for a closed file, the file is opened implicitly for input without the INTERACTIVE attribute.
program COPY;
var
  INFILE, OUTFILE : TEXT;
  BUF : STRING(100);
begin
  RESET(INFILE);
  REWRITE(OUTFILE);
  while not EOF(INFILE) do
    begin
      READ(INFILE, BUF);
      WRITELN(OUTFILE, BUF);
      (*ignore characters after column 100 in each line *)
      READLN(INFILE)
    end.
end.

Figure 31. Using the procedure READLN

7.4.9 Text File WRITE

The WRITE procedure outputs data to a text file beginning at the current position of the file pointer. If WRITE is called for a closed file, the file is opened implicitly for output.

If during a call to WRITE, the length of the logical record being produced becomes equal to the logical record length (LRECL) of the text file, the record is completed and the remaining data is placed on a new record.

program DOWRITE;
var
  OUTFILE : TEXT;
  R: array[1..10] of record
    NAME: STRING(25);
    AGE: 0..99;
    WEIGHT: REAL
  end;
I: 1..10;
begin
  REWRITE(OUTFILE);
  for i := 1 to 10 do
    with R[i] do
      begin
        WRITE(OUTFILE, NAME, ', ', AGE, '; ', WEIGHT, ': ',);
        WRITELN(OUTFILE)
      end.
end.

Figure 32. Using WRITE on TEXT files

7.4.10 The WRITELN Procedure

The WRITELN procedure is applicable only to text files intended for output. It causes the current logical record being produced to be completed so that the next output operation will begin a new logical record.

If the record format of the file is fixed (RECFM=F), WRITELN will fill the remainder of the current record with blanks. For variable length records (RECFM=V), the record length is set to the number of bytes currently occupied by the record.

If WRITELN is called for a closed file, the file is opened implicitly for output.

program DOUBLESPACE;
var
  FILEIN, FILEOUT : TEXT;
  BUF : STRING;
begin
  REWRITE(FILEOUT);
  RESET(FILEIN);
  while not EOF(FILEIN) do
    begin
      READLN(FILEIN, BUF);
      WRITELN(FILEOUT, BUF);
      (*insert blank line *)
      WRITELN(FILEOUT)
    end.
end.

Figure 33. Using the WRITELN procedure

7.5 RECORD FILES

All non-TEXT files in Pascal/VS are record files by definition. Input and output operations on record files are done on a logical record basis instead of on a character basis.

The logical record length (LRECL) of a file must be at least large enough to contain the file's base component; otherwise, an execution time error will occur when the file is opened. For example, a file variable declared as 'file of INTEGER' will require the associated physical file to have a logical record length of at least 4 bytes.

If a file has fixed length records (RECFM=F) and the logical record length is larger than necessary to contain the files component type, then the extra space in each logical record is wasted.
7.5.1 Opening a Record File

A closed file is opened automatically when the first operation is performed on it. The procedures GET and READ will open it for input; PUT and WRITE will open it for output. To open a file explicitly, the procedures RESET, REWRITE, and OPEN are provided.

The procedure RESET is used to open a file for input. This procedure allocates a buffer, reads the first logical record of the file into the buffer, and positions the file pointer at the beginning of the buffer. Therefore, given a record file F, the execution of the statement 'RESET(F)' would imply that the term 'F->' would reference the first component of the file. If a RESET operation is performed on an open file, the file is closed and then reopened.

The procedure REWRITE is used to open a file for output. The file pointer is positioned at the beginning of an empty buffer. If the file is already open it is closed prior to being reopened.

7.5.2 Record File PUT

The PUT procedure causes the file record that was assigned to the output buffer via the file pointer to be effectively written to the associated physical file. Each call to PUT for the case of record files produces one logical record.

```
program EXAMPLE;
var
 F : file of record
    NAME : STRING(25);
    AGE : 0..99;
    WEIGHT: REAL;
    SEX : (MALE,FEMALE)
end;
begin
 REWRITE(F);
 F->.NAME := 'John F. Doe';
 F->.AGE := 36;
 F->.WEIGHT := 160.0;
 F->.SEX := MALE;
 PUT(F);
end...
```

Figure 34. Using PUT on record files

7.5.3 Record File GET

The GET procedure causes the next sequential file record to be placed in the input buffer referenced by the file pointer. Each call to GET for the case of record files reads one logical record.

```
program EXAMPLE;
var
 F : file of record
    NAME : STRING(25);
    AGE : 0..99;
    WEIGHT: REAL;
    SEX : (MALE,FEMALE)
end;
begin
 RESET(F);
 while not EOF(F) do begin
   WRITE( 'Name: ', F->.NAME);
   WRITE( 'Age: ', F->.AGE:3);
   WRITELN;
   GET(F)
 end
end
```

Figure 35. Using GET on record files

7.5.4 End of File Condition

The end-of-file condition occurs when a call to GET or READ is attempted on a record file (open for input) when no more logical records remain in the file. The function EOF is used to test this condition.

7.5.5 Record File READ

As documented in the language manual, the statement

```
READ(F,V)
```

is equivalent to

```
begin
 V := F->;
 GET(F)
end
```

where F and V are declared as follows:

```
var F : file of t;
V : t;
```
If file F is not open when READ is called, it will be opened implicitly for input.

7.5.6 Record File WRITE

As documented in the language manual, the statement

\[
\text{WRITE}(F,V)
\]

is equivalent to

\[
\begin{align*}
\text{begin} & \\
F-& := V; & \\
\text{PUT}(F) & \\
\text{end}
\end{align*}
\]

where F and V are declared as follows:

\[
\begin{align*}
\text{var } F: & \text{ file of } t; \\
V: & t;
\end{align*}
\]

If file F is not open when WRITE is called, it will be opened implicitly for output.

The procedure CLOSE is provided to close a file explicitly. CLOSE is predeclared as follows:

\[
\text{procedure } \text{CLOSE} (\quad \text{var } F: \text{ filetype} ); \text{ EXTERNAL;}
\]

7.7 THE OPEN PROCEDURE

The OPEN procedure is a generalized form of the procedures RESET and REWRITE. OPEN is predeclared in the following fashion:

\[
\text{procedure } \text{OPEN} (\quad \text{var } F: \text{ filetype}; \text{ const } \text{OPTIONS: STRING}); \text{ EXTERNAL;}
\]

The second parameter of the OPEN procedure is a string expression. This string contains a list of options which are read at execution time. These options determine how the file is to be opened and what attributes it is to have.

The data in the string parameter has the syntax shown in the following figure:

```
option-string:
- > [option] ->
     `, `     
option:
- > DDNAME = name ->
- > BLKSIZE = n ->
- > LRECL = n ->
- > RECFM = c ->
- > INTERACTIVE ->
- > RESET ->
- > REWRITE ->
- > PDSIN,MEMBER=name ->
- > PDSOUT,MEMBER=name ->
```

Figure 37. Syntax of string parameter of OPEN

The options RESET, REWRITE, INTERACTIVE, PDSIN, and PDSOUT are mutually exclusive. If none of these options appear in the option string, REWRITE will be assumed by default.

7.6 CLOSING A FILE

All files which are declared in the body of a routine are closed implicitly when the routine returns to its invoker. All files which are open when the program terminates, whether normally or abnormally, will be closed automatically by the Pascal/VS runtime environment.

If the procedures RESET, REWRITE, or OPEN are applied to an open file, the file is closed prior to being reopened.

46 Pascal/VS Programmer's Guide
The following is a description of each option.

**DDNAME=**name

This attribute signifies that the physical file to be associated with the file variable has the ddname indicated by "name". This new ddname will remain associated with the file variable even if the file is closed and then re-opened. It can only be changed by another call to OPEN with the DDNAME attribute specified.

If this option is not specified, then the ddname to be associated with the file is derived from the first eight characters of the file variable name (first parameter of OPEN).

**BLKSIZE=n**

This attribute is used to specify a physical block size to be associated with an output file. This value (indicated by "n") will override a BLKSIZE specification on the ddname definition.

**LRECL=n**

This attribute is used to specify a logical record length to be associated with an output file. This value (indicated by "n") will override a LRECL specification on the ddname definition.

**RECFM=C**

This attribute is used to specify a record format to be associated with an output file. The only valid record formats that may be specified are

F, FB, FA, FBA, V, VB, VA, VBA

This specification (indicated by "C") will override a RECFM specification on the ddname definition.

**INTERACTIVE**

This attribute indicates that the file is to be opened for input as an interactive file. See "Opening a Text File" on page 40 for a description of interactive files.

**RESET**

This attribute indicates that the file is to be opened for input. A call to OPEN with this attribute performs the same function as a call to the procedure RESET.

**REWRITE**

This attribute indicates that the file is to be opened for output. A call to OPEN with this attribute performs the same function as a call to the procedure REWRITE.

**PDSIN,MEMBER=**name

These attributes indicate that the file to be opened is an OS partitioned data set (PDS). The member to be accessed is indicated by "name". PDSIN indicates that the member is to be opened for input; PDSSOUT indicates that it is to be opened for output. These two operations perform in the same manner as the corresponding RESET and REWRITE operations.

```pascal
program EXAMPLE;
var
  PDS : TEXT;
  MEMBER : STRING(8);
  BUF : packed array[1..80] of CHAR;
begin
  OPEN(INPUT,'INTERACTIVE');
  READLN(MEMBER);
  while not EOF(INPUT) do begin
    OPEN(PDS,'DDNAME=SYSLIB,PDSIN,MEMBER='||MEMBER);
    while not EOF(PDS) do begin
      READLN(PDS,BUF);
      WRITELN(BUF);
    end;
    READLN(MEMBER)
  end.
end.
```

Figure 38. Using the OPEN procedure
In a CMS environment, members of MACLIBs may be accessed as partitioned data sets via the OS simulation facilities. A ddname is assigned to the MACLIB file with the FILEDEF command; the file name of the maclib must then appear in a "GLOBAL MACLIB" command.

For example, in order to access the file "MYLIB MACLIB A" as a partitioned data set with ddname "LIB" from a Pascal/VS program, the following commands would be executed prior to executing the program.

```
FILEDEF LIB DISK MYLIB MACLIB A
GLOBAL MACLIB MYLIB
```

Two or more MACLIBs may be accessed as though they were concatenated by using the CONCAT option of the FILEDEF command. For example, in order to access the MACLIBs "M1", "M2", and "M3" as a concatenated partitioned data set with ddname "LIB", the following commands would be executed prior to executing the Pascal/VS program.

```
FILEDEF LIB DISK M1 MACLIB A
FILEDEF LIB DISK M2 MACLIB A (CONCAT
FILEDEF LIB DISK M3 MACLIB A (CONCAT
GLOBAL MACLIB M1 M2 M3
```
8.1 READING A PASCAL/VS TRACE BACK

The Pascal/VS trace facility provides useful information while debugging programs. It gives you a list of all of the routines in the procedure chain.

For each routine the following information is given.

- The name of the routine.
- The statement number of the last statement to be executed in the routine (i.e. the statement number of the call to the next routine in the chain).
- The address in storage where the generated code for the statement begins.
- The name of the module in which the routine is declared.

The trace routine may be invoked in four different ways. You may invoke trace by placing in your source program a call to the pre-defined routine called TRACE. An example is given in Figure 39 on page 50. In the example starting at the bottom we see that Pascal/VS called the user's main program in the module named HASHASEG. Statement 24 of the main program contains the call to READ_ID, statement 3 of READ_ID contains the call to SEARCH_ID, and so on.

A trace will be produced when a program error occurs. An example is given in Figure 40 on page 50. There is an error message indicating a fixed point overflow. The traceback tells us the routine and the statement number where the error occurred. Looking at the trace we see that the error occurred at statement 3 in routine FACTORIAL on the third recursive call.

A trace will be produced when a checking error occurs. A checking error occurs when code produced by the compiler detects an invalid condition such as a subscript range error. (See "CHECK/NOCHECK" on page 29 for a description of compiler generated checks.) Figure 41 on page 50 is an example of a traceback that occurred from a checking error. The first line of the trace identifies the particular checking error that occurred. Looking at the trace we see that the error occurred at statement 4 in routine TRANSLATE.

A trace will be produced when an I/O error occurs. Figure 42 on page 50 is an example of this. In this case, statement 3 of routine INITIALIZE attempted to open a file for which no DDNAME definition existed.

Due to optimization performed by the compiler, the code which tests for an error condition may be moved back several statements. Thus, when a runtime error occurs, the statement number indicated in the traceback might be slightly less than the number of the statement from which the error was generated.
Figure 39. Trace called by a user program

Figure 40. Trace call due to program error

Figure 41. Trace call due to checking error

Figure 42. Trace call due to I/O error
8.2 RUN TIME CHECKING ERRORS

The following is a list of the possible checking errors that may occur in a Pascal/VS program at run time.

LOW BOUND
Either a subscript or a subrange variable is being assigned a value less than the lower bound of the allowed range.

HIGH BOUND
Either a subscript or a subrange variable is being assigned a value greater than the upper bound of the allowed range.

NIL POINTER
An attempt was made to reference a variable from a pointer using the value NIL.

CASE ERROR
A case expression has a value other than any of the declared case labels and there is no otherwise clause.

STRING CONCATENATION
The concatenation of two strings results in a string greater than 255 characters in length.

STRING TRUNCATION
There was an attempt to assign to a string a value which has more characters than the maximum length of the string.

ASSERTION FAILED
An assert statement was executed in which its associated boolean expression evaluated to the value FALSE.

8.3 SYMBOLIC VARIABLE DUMP

When a program error or checking error occurs, a symbolic dump of all variables which are local to the routine in which the error occurred may be produced. This dump will be produced if two conditions are met:

- The source module containing the code from which the error occurred was compiled with the DEBUG option.
- The Pascal/VS debug library was included in the generation of the associated load module.

The dump is written to file OUTPUT.
Debug is a tool that allows programmers to quickly debug Pascal/VS programs without having to write debug statements directly into their source code. Basic functions include tracing program execution, viewing the runtime values of program variables, breaking at intermediate points of execution, and displaying statement frequency counting information. The programmer uses Pascal/VS source names to reference statements and data.

In order to use Debug, you must follow these four steps:

- Compile the module to be debugged with the DEBUG option. Modules that have been compiled with the DEBUG option can be linked with modules that have not been compiled with the DEBUG option.
- When link editing your program, include the debug library. (It must be located ahead of the runtime library in search order).
- Ddname INPUT must be allocated to your terminal, or to the data set from which Debug commands are to be read. Likewise, the ddname OUTPUT must be allocated to your terminal.
- When executing the load module, specify 'DEBUG,' as a parameter. This will cause the debug environment to become active, and, if INPUT has been allocated to your terminal, you will be immediately prompted for a Debug command. In the Debug environment the user may issue Debug commands and examine variables for those modules which were compiled with the DEBUG option.

9.1 QUALIFICATION

A qualification consists of a module name and a routine name. Debug uses the current qualification as the default to retrieve information for commands. The current qualification consists of the name of the routine and associated source module which was last interrupted when the debugger gained control.

At the start of a Debug session, the current qualification is the name of the module containing the main program, and the main program itself.

9.2 COMMANDS

This section describes the commands that a user may issue with the Debug facility. Every command may be abbreviated to one letter if desired except the QUIT and CLEAR commands which have no abbreviation. Square brackets ('[' and ']') are used in the command description to indicate optional parts of the command.

---

Under CMS, the debug library is included if the DEBUG option is specified when invoking PASCUMOD. (see "How to Build a Load Module" on page 6.)

Under TSO, the debug library is included by specifying the DEBUG keyword operand when invoking the PASCUMOD clist. (see "How to Build a Load Module" on page 12.)
9.2.1 BREAK Command

Command Format:
BREAK [[module/] routine/] stmtno

Minimum Abbreviation:
B

Where:
module is the name of a Pascal/VS module.
routine is the name of a procedure or function in the module.
stmtno is a number of a statement in the designated routine.

This command causes a breakpoint to be set at the indicated statement. The program is stopped before the statement is executed.

The module and/or routine may be omitted in which case the defaults are taken from the current qualification. stmtno is the number of the statement on which to stop in the specified routine of the specified module. The statement numbers are found on the source listing.

A maximum of 8 breakpoints may be set at any one time.

9.2.2 CLEAR Command

Command Format:
CLEAR

Minimum Abbreviation:
CLEAR

There are no operands.

The CLEAR command is used to remove all breakpoints.
### 9.2.3 CMS Command

<table>
<thead>
<tr>
<th>Command Format:</th>
<th>CMS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Abbreviation:</td>
<td>C</td>
</tr>
<tr>
<td>There are no operands.</td>
<td></td>
</tr>
</tbody>
</table>

This command activates the CMS subset mode. If the program is not being run under CMS, the command is ignored.

### 9.2.4 DISPLAY Command

<table>
<thead>
<tr>
<th>Command Format:</th>
<th>DISPLAY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Abbreviation:</td>
<td>D</td>
</tr>
</tbody>
</table>

The DISPLAY command is used to display information about the current Debug session at the user's terminal. The information displayed is:

- the current qualification,
- where the user's program will resume execution upon the GO command,
- the current status of Counts,
- the current status of Tracing.
### 9.2.5 DISPLAY BREAKS Command

**Command Format:**
```
DISPLAY BREAKS
```

**Minimum Abbreviation:**
```
D B
```

There are no operands.

The DISPLAY BREAKS command is used to produce a list of all breakpoints which are currently set.

### 9.2.6 DISPLAY EQUATES Command

**Command Format:**
```
DISPLAY EQUATES
```

**Minimum Abbreviation:**
```
D E
```

There are no operands.

The DISPLAY EQUATE command is used to produce a list of all equate symbols and their current definitions.
9.2.7 EQUATE Command

**Command Format:**
EQUATE identifier [data]

**Minimum Abbreviation:**
E identifier [data]

**Where:**
- identifier is a Pascal/V5 identifier.
- data is a command which the identifier is to represent.

This command causes the data to replace the identifier whenever the identifier is first token in a command.

**Examples**
equate x ,r->.b[2]->
eq y break procx/4
eq z

The first example demonstrates how a user may examine a variable without having to retype a long string every time. The next example demonstrates a way to develop a synonym for a command. The third example shows how to remove an equate.

9.2.8 GO Command

**Command Format:**
GO

**Minimum Abbreviation:**
G

There are no operands.

This command causes the program to either start or resume executing. The program will continue to execute until one of the following events occurs:

- breakpoint
- program error
- normal program exit

A breakpoint or program error will return the user to the Debug environment.
### 9.2.9 Help Command

<table>
<thead>
<tr>
<th>Command Format:</th>
<th>?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Abbreviation:</td>
<td>?</td>
</tr>
<tr>
<td>There are no operands.</td>
<td></td>
</tr>
</tbody>
</table>

The Help command lists all Debug commands.

### 9.2.10 LISTVARS Command

<table>
<thead>
<tr>
<th>Command Format:</th>
<th>LISTVARS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum Abbreviation:</td>
<td>L</td>
</tr>
<tr>
<td>There are no operands.</td>
<td></td>
</tr>
</tbody>
</table>

This command displays the values of all variables which are local to the currently active routine.
### 9.2.11 Qualification Command

**Command Format:**

```
QUAL [module /] [routine]
```

**Minimum Abbreviation:**

```
Q [module /] [routine]
```

**Where:**

- `module` is the name of a Pascal/V5 module.
- `routine` is the name of a procedure or function in the module.

If the user does not specify a module and/or a routine name the defaults are taken from the current qualification. The defaults are applied as follows:

- the module name defaults to the current qualification.
- the routine defaults to the main program if the associated module is a program module, or to the outer-most lexical level if the module is a segment module.

The lexical scope rules of Pascal are applied when viewing variables. The current qualification provides the basis on which program names are resolved. If there is no activation of the routine available (no invocations) the user may not display local variables for that routine.

Qualification may be changed at any time during a Debug session. When a breakpoint is encountered, the qualification is automatically set to the module and the routine in which the breakpoint was set.

### 9.2.12 QUIT Command

**Command Format:**

```
QUIT
```

**Minimum Abbreviation:**

```
QUIT
```

There are no operands.

This command causes the program to end. It is similar to a normal program exit. The user is returned to the operating system.
**9.2.13  RESET Command**

**Command Format:**
RESET [[module/routine/] stmtno
Minimum Abbreviation:
R [[module/routine/] stmtno
Where:
module is the name of a Pascal/VS module.
routine is the name of a procedure or function in the module.
stmtno is a number of a statement in the designated routine.

The RESET command is used to remove a breakpoint. The defaults are the same as the BREAK command.

---

**9.2.14  SET ATTR Command**

**Command Format:**
SET ATTR [ ON OFF ]
Minimum Abbreviation:
S A [ ON OFF ]

The SET ATTR command is used to set the default way in which variables are viewed. The ON parameter specifies that variable attribute information will be displayed by default. The OFF parameter specifies that variable attribute information will not be displayed by default. The default may be overridden on the variable viewing command.
9.2.15 SET COUNT Command

Command Format:

SET COUNT [ON OFF]

Minimum Abbreviation:

S C [ON OFF]

The SET COUNT command is used to initiate and terminate statement counting. Statement counting is used to produce a summary of the number of times every statement is executed during program execution. The summary is produced at the end of program execution and is written to the standard file OUTPUT. Statement counting may also be initiated with the runtime COUNT option.

9.2.16 SET TRACE Command

Command Format:

SET TRACE [ON OFF]

Minimum Abbreviation:

S T [ON OFF]

The SET TRACE command is used to either activate or deactivate program tracing. Program tracing provides the user with a list of every statement executed in the program. This is useful for following the execution flow during execution.
9.2.17 TRACE Command

Command Format:
TRACE
Minimum Abbreviation:
T
This command has no operands.

The TRACE command is used to produce a routine trace at the user's terminal. The procedures on the current invocation chain are listed along with the most recently executed statement in each.

9.2.18 Viewing Variables

Command Format:
, variable [(option [])] [ ]
Where:
variable is a Pascal variable. See the chapter entitled "Variables" in the Pascal/VS Reference Manual for the syntax of a variable.
option is either ATTR or NOATTR.

This command allows the user to obtain the contents of a variable during program execution.

The static scope rules that apply to the current qualification are applied to the specified variable. If the variable is found to be a valid reference, then its value is displayed. If the name cannot be resolved within the current qualification, the user is informed that the name is not found. If the name resolves to an automatic variable for which no activation currently exists the user is informed that the variable cannot be displayed.

As can be seen from the following examples, array elements, record fields, and dynamic variables may all be viewed. Variables are formatted according to their data type. Entire records, arrays and spaces are displayed as a hexadecimal dump. The user may view an array slice by specifying fewer indices than the declared dimension of the array. The missing indices must be the rightmost ones.

The options ATTR or NOATTR can follow a left parenthesis. The default is taken from the SETATTR command. The initial default is NOATTR. If the user gives ATTR as an option, attributes of the variable are displayed along with the value of the variable. The attributes are the data type, memory class, length if relevant, and the routine where the variable was declared.

Note: a subscripting expression may only be a variable or constant: that is, it may contain no operators. Thus, such a reference as

, a[b->[j]]

is valid (at least syntactically), but the reference

, a[i+3]
is not a valid reference because the subscripting expression is not a variable or constant.

Examples

', a
', p->
', p->[b
', b[x].int (ATTR
', p->[x,y].b->.a[i]

9.2.19 Viewing Memory

Command Format:

', hex-string [ : length ]

Where:

hex-string is a number in hexadecimal notation.
length is an integer.

This command is used to display the contents of a specific memory location. Memory beginning at the byte specified by the hex string is dumped for the number of bytes specified by the length field. If the length is not specified memory is dumped for 16 bytes. The dump is in both hex and character formats.

The hex string must be an hexadecimal number surrounded by single quotes and followed by an 'x' (eg. '35D05'X). The length is specified in decimal.

Examples

', '20000'X
', '46cf0'X : 100
9.2.20 WALK Command

Command Format:

WALK

Minimum Abbreviation:

W

There are no operands.

This command causes the program to either start executing or resume executing. The program execution will continue for exactly one statement and then the user will be returned to Debug. This command is useful for single stepping through a section of code.
Figure 43. Sample program for Debug session

The following series of figures is a sample Debug terminal session that demonstrates breakpoints and viewing variables. User commands are in lower case; system responses are highlighted. The program being executed is shown in Figure 43.

Figure 47. Debug error messages
This section describes the rules that the Pascal/VS compiler employs in mapping variables to storage locations.

### 10.1 Automatic Storage

Variables declared locally to a routine via the `var` construct are assigned offsets within the routine’s dynamic storage area (DSA). There is a DSA associated with every routine of the program plus one for the main program itself. The DSA of a routine is allocated when the routine is called and is deallocated when the routine returns.

### 10.2 Internal Static Storage

For source modules that contain variables declared STATIC, a single unnamed control section ('private code') is associated with the source module in the resulting text deck. Each variable declared via the STATIC construct, regardless of its scope, is assigned a unique offset within this control section.

### 10.3 Def Storage

Each def variable which is initialized by means of the `value` declaration will generate a named control section (csect). Each def variable which is not initialized will generate a named common section. The name of the section is derived from the first eight characters of the variable's name.

### 10.4 Dynamic Storage

Pointer qualified variables are allocated dynamically from heap storage by the procedure 'NEW'. Such variables are always aligned on a doubleword boundary.

### 10.5 Record Fields

Fields of records are assigned consecutive offsets within the record in a sequential manner, padding where necessary for boundary alignment. Fields within unpacked records are aligned in the same way as variables are aligned. The fields of a packed record are aligned on a byte boundary regardless of their declared type.

### 10.6 Data Size and Boundary Alignment

A variable defined in an Pascal/VS source module is assigned storage and aligned according to its declared type.

#### 10.6.1 The Predefined Types

The table in Figure 48 displays the storage occupancy and boundary alignment of variables declared with a predefined type.

<table>
<thead>
<tr>
<th>DATA TYPE</th>
<th>SIZE in bytes</th>
<th>BOUNDARY ALIGNMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALFA</td>
<td>8</td>
<td>BYTE</td>
</tr>
<tr>
<td>ALPHA</td>
<td>16</td>
<td>BYTE</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>1</td>
<td>BYTE</td>
</tr>
<tr>
<td>CHAR</td>
<td>1</td>
<td>BYTE</td>
</tr>
<tr>
<td>INTEGER</td>
<td>4</td>
<td>FULL WORD</td>
</tr>
<tr>
<td>REAL</td>
<td>8</td>
<td>DOUBLE WORD</td>
</tr>
<tr>
<td>STRING(len)</td>
<td>len+1</td>
<td>BYTE</td>
</tr>
</tbody>
</table>

Figure 48. Storage mapping for predefined types
10.6.2 Enumerated Scalar

An enumerated scalar variable with 256 or fewer possible distinct values will occupy one byte and will be aligned on a byte boundary. If the scalar defines more than 256 values then it will occupy a half word and will be aligned on a half word boundary.

10.6.3 Subrange Scalar

A subrange scalar that is not specified as packed will be mapped exactly the same way as the scalar type from which it is based.

A packed subrange scalar is mapped as indicated in the table of Figure 49. Given a type definition T as:

```
type T = packed i..j;
and
const I = ORD(i);
J = ORD(j);
```

<table>
<thead>
<tr>
<th>Range of I .. J</th>
<th>SIZE in bytes</th>
<th>ALIGNMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>0..255</td>
<td>1</td>
<td>BYTE</td>
</tr>
<tr>
<td>-128..127</td>
<td>1</td>
<td>BYTE</td>
</tr>
<tr>
<td>-32768..32767</td>
<td>2</td>
<td>HALF WORD</td>
</tr>
<tr>
<td>0..65535</td>
<td>2</td>
<td>HALF WORD</td>
</tr>
<tr>
<td>otherwise</td>
<td>4</td>
<td>FULL WORD</td>
</tr>
</tbody>
</table>

Figure 49. Storage mapping of subrange scalars

Each entry in the first column in the above table is meant to include all possible sub-ranges within the specified range. For example, the range 100..250 would be mapped in the same way as the range 0..255.

10.6.4 RECORDS

An unpacked record is aligned in such a way that every field of the record is properly aligned on its required boundary. That is, records are aligned on the boundary required by the field with the largest boundary requirement.

For example, record A below will be aligned on a full word because its field A1 requires a full word alignment; record B will be aligned on a double word because it has a field of type REAL; record C will be aligned on a byte.

```
type
  A = record (*full word aligned*)
  A1 : INTEGER;
  A2 : CHAR
end;
B = record (*double word aligned*)
  B1 : A;
  B2 : REAL;
  B3 : BOOLEAN
end;
C = record (*byte aligned*)
  C1 : packed 0..255;
  C2 : ALPHA
end;
```

Figure 50. Alignment of records

Packed records are always aligned on a byte boundary;

10.6.5 ARRAYS

Consider the following type definition:

```
type
  A = array [ s ] of t
where type s is a simple scalar and t is any type.
```

A variable declared with this type definition would be aligned on the boundary required for data type 't'. With the exception noted below, the amount of storage occupied by this variable is computed by the following expression:

```
(ORD(HIGHEST(s)) - ORD(LOWEST(s)) + 1) * SIZEOF(t)
```

The above expression is not necessarily applicable if 't' represents an unpacked record type. In this case, padding will be added, if necessary, between each element so that each element will be aligned on a boundary which meets the requirements of the record type.

Packed arrays are mapped exactly as unpacked arrays, except padding is never inserted between elements.

A multi-dimensional array is mapped as an array of array(s). For example the
following two array definitions would be mapped identically in storage.

```
array [ i .. j, m .. n ] of t
array [ i .. j ] of
array [ m .. n ] of t
```

### 10.6.6 FILES

File variables occupy 64 bytes and are aligned on a full word boundary.

### 10.6.7 SETs

Sets are represented internally as a string of bits: one bit position for each value that can be contained within the set.

To adequately explain how sets are mapped, two terms will need to be defined: The base type is the type to which all members of the set must belong. The fundamental base type represents the non-subrange scalar type which is compatible with all valid members of the set. For example, a set which is declared as

```
set of '0'..'9'
```

has the base defined by '0'..'9'; and a fundamental base type of CHAR.

Any two unpacked sets which have the same fundamental base type will be mapped identically (that is, occupy the same amount of storage and be aligned on the same boundary). In other words, given a set definition:

```
type
  S = set of s;
  T = set of t;
```

where s is a non-subrange scalar type and t is a subrange of s: both S and T will have the same length and will be aligned in the same manner.

Sets always have zero origin; that is, the first bit of any set corresponds to a member with an ordinal value of zero (even though this value may not be a valid set member).

Unpacked sets will contain the minimum number of bytes necessary to contain the largest value of the fundamental base type. Packed sets occupy the minimum number of bytes to contain the largest valid value of the base type. Thus, variables A and B below will both occupy 256 bits.

```
var
  A : set of CHAR;
  B : set of '0'..'9';
```

Variables C and D will both occupy 16 bits; variable E will occupy 8 bits.

```
var
  C : set of (C1,C2,C3,C4,C5,C6, C7,C8,C9,C10,C11,C12 C12,C13,C14,C15,C16);
  D : set of C1..C8;
  E : packed set of C1..C8;
```

A set type with a fundamental base type of INTEGER is restricted so that the largest member to be contained in the set may not exceed the value 255; therefore, such a set will occupy 256 bits.

Thus, variables U and V below will both occupy 256 bits; variable W will occupy 21 bits; variable X will occupy 32 bits.

```
var
  U : set of 0..255;
  V : set of 10..20;
  W : packed set of 10..20;
  X : packed set of 0..31;
```

Given that M is the number of bits required for a particular set, the table in Figure 51 indicates how the set will be mapped in storage.

Figure 51. Storage mapping of SETs

### 10.6.8 SPACES

A variable declared as a space is aligned on a byte boundary and occupies the number of bytes indicated in the length specifier of the type definition. For example, the variable S declared below occupies 1000 bytes of storage.

```
var S: space [1000] of INTEGER;
```
11.1 LINKAGE CONVENTIONS

Pascal/VS uses standard OS linkage conventions with several additional restrictions. The result is that Pascal/VS may call any program that requires standard conventions and may be called by any program that adheres to the additional Pascal/VS restrictions.

On entry to a Pascal/VS routine the contents of relevant registers are as follows:

- Register 1 - points to the parameter list
- Register 12 - points to the Pascal/VS Communication Work Area (PCWA)
- Register 13 - points to the save area provided by the caller
- Register 14 - return address
- Register 15 - entry point of called routine

Pascal/VS requires that the parameter register (R1) be pointing into the Dynamic Storage Area (DSA) stack in such a way that 144 bytes prior to the R1 address is an available save area.

11.2 REGISTER USAGE

The table in Figure 52 describes how each general register is used within a Pascal/VS program. The floating point registers are used for computation on data of type REAL.

<table>
<thead>
<tr>
<th>register(s)</th>
<th>purpose(s)</th>
</tr>
</thead>
</table>
| 0,1         | - temporary work registers for the compiler  
|             | - standard linkage usage on calls          |
| 3,4,5,6,7,8,9 | - registers assigned by the compiler for computation and for data base registers |
| 2,10        | - code base registers of the currently executing routine |
| 11          | - address of DSA of active routine at outermost lexical level |
| 12          | - always points to Pascal/VS Communication Work Area |
| 13          | - always points to the local DSA |
| 14,15       | - temporary work registers for the compiler  
|             | - standard linkage usage on calls |

Figure 52. Register usage
11.3 **DYNAMIC STORAGE AREA**

On entry to a procedure or function, an area of memory called a **Dynamic Storage Area (DSA)** is allocated. This area is used to contain save areas, local variables and compiler generated temporaries. **Pascal/VS** requires a minimum DSA of 144 bytes; if the routine has parameters or local variables, more space is needed.

The first 72 bytes are generally used according to standard OS linkage conventions. The first word is used to copy the previous data base register at the current procedure nesting level.

Figure 53. DSA format
11.4 ROUTINE INVOCATION

Each invocation of a Pascal/VS routine must acquire a dynamic storage area (DSA) (see "Dynamic Storage Area" on page 74). This storage is allocated and deallocated in a LIFO (last in/first out) stack. If the stack should become filled to its capacity, a storage overflow routine will attempt to obtain another stack from which storage is to be allocated.

Every DSA must be at least 144 bytes long; this is the storage required by Pascal/VS for a save area. The routine's local variables and parameters are mapped within the DSA starting at offset 144.

Upon entering a routine, register 1 points 144 bytes into the routine's DSA, which is where the parameters passed in by the caller reside. This implies that the calling routine is responsible for allocating a portion of the DSA required by the routine being called, namely 144 bytes plus enough storage for the parameter list. This portion of storage is actually an extension of the caller's DSA.

In general, the DSA of a routine consists of five sections:

1. The local save area (144 bytes).
2. Parameters passed in by the caller.
3. Local variables required by the routine.
4. A save area required by any routine that will be called.
5. Storage for the largest parameter list to be built for a call.

Sections 1 and 2 are allocated by the calling routine; sections 3, 4, and 5 are allocated by the prologue of the routine to which the DSA belongs.

Upon invocation, register 13 points to the base of the DSA of the caller, which is where the caller's save area is located. The new value of register 13 may be computed by subtracting 144 from the value in register 1. Figure 54 illustrates the condition of the stack and relevant registers immediately at the start of a routine.

Code Generation for the IBM/370 75
11.5 PARAMETER PASSING

Pascal/VS passes parameters in several different ways depending on how the parameter was declared. In every case, register 1 contains the address of the parameter list.

The parameter list is aligned on a doubleword boundary and each parameter is aligned on its proper boundary. Addresses are aligned on word boundaries.

11.5.1 Passing by Read/Write Reference

This mechanism is indicated by use of the reserved word var in the routine heading. Actual parameters passed in this way may be modified by the invoked routine.

The parameter list contains the address of the actual parameter.

Routine Heading:

procedure PROC(var I: INTEGER);

Routine Invocation:

PROC(J);

Parameter list:

address of J

Figure 55. Passing by Read/Write reference

11.5.2 Passing by Read-Only Reference

This mechanism is indicated by use of the reserved word const in the routine heading. Actual parameters passed in this way may not be modified by the invoked routine.

The parameter list contains the address of the actual parameter.

Routine Heading:

procedure PROC(const I: INTEGER);

Routine Invocation:

PROC(J+5);

Parameter list:

address of a memory location which contains the value of J+5.

Figure 56. Passing by Read-only reference

11.5.3 Passing by Value

This mechanism is the default way in which parameters are passed. Parameters passed in this way are treated as if they are pre-initialized local variables in the invoked routine. Any modification to these parameters by the invoked routine will not be reflected back to the caller. If the actual parameter is a scalar, pointer, or set, then the parameter list will contain the value of the actual parameter. If the actual parameter is an array, record, space, or &string, then the parameter list will contain the address of the actual parameter. In the latter case, the called procedure will copy the parameter into its local storage.

Routine Heading:

procedure PROC(I: INTEGER;
A: ALPHA);

Routine Invocation:

PROC(J,'alpha');

Parameter list:

value of J
address of 'alpha

Figure 57. Passing by value
11.5.4 Passing Procedure or Function Parameters

For procedures or functions which are being passed as parameters, the address of the routine is placed in the parameter list.

**Routine Heading:**

```pascal
procedure PROC(
    function X(Y: REAL): REAL);
```

**Routine Invocation:**

```pascal
PROC(COS);
```

**Parameter list:**
- address of COS routine

*Figure 58. Passing parameters*

11.5.5 Function Results

Pascal/VS functions have an implicit parameter which precedes all specified parameters. This parameter contains the address of the memory location where the function result is to be placed.

**Routine Heading:**

```pascal
function FUNC(C: CHAR): INTEGER;
```

**Routine Invocation:**

```pascal
I := FUNC('L');
```

**Parameter list:**
- address of returned integer result
- value of character 'L'

*Figure 59. Function results*
11.6 PROCEDURE/FUNCTION FORMAT

Every Pascal/VS procedure or function is arranged in the order shown below. Register 2 is the code base register for the first 4K bytes of the routine body. If the routine occupies more than 4K bytes, register 10 is used as the code base register for the second 4K bytes. If a routine exceeds 8K bytes of storage, the compiler will diagnose it as a terminal error.

Figure 60. Routine format

11.7 PCWA

The Pascal Communications Work Area is always addressable from register 12. This area of memory is used to contain global information about the execution of the program.

The area is divided into two parts, each is 2048 bytes in length. The first part contains data that needs to be addressable; the second is composed of the small routines used to augment the generated code. An example is the routine that is used to concatenate two strings.

**Figure 61. Pascal Communications Work Area**

- **end of stack**: a pointer to the end of the current DSA stack.
- **current stack**: a pointer to the top of the current DSA stack.
- **flags 1**: reserved for future use.
- **flags 2**: flags used to enable runtime features.
- **return code**: the value assigned by the last execution of `RETCODE` or zero if `RETCODE` has not been called.
- **pointer to files**: a pointer to the first file that has been opened but never closed.
- **pointer to parms**: a pointer to the parameter list passed to the program.
- **module link**: a pointer to the head of a chain that links modules together as directed by the interactive debugger.
- **ext. save area**: contains the pointer to the save area for the caller of the Pascal program.
- **level display**: a stack of 8 base registers that contain the addresses of the DSAs that are available to the executing routine.
- **debug temp**: a temporary used by the symbolic debugger.
- **floating pt temp**: a temporary used in conversion between floating point numbers and integers.
- **conversion const1**: a constant that contains the floating point value zero.
- **conversion const2**: a constant that contains the floating point value of $2^{31} - 1$ in an unnormalized form.
- **set mask**: eight bytes that contain masks used in set operations.
- **temp dsa save**: a temporary used during execution errors.
- **error recovery save area**: used as a register save area when a program error or checking error occurs.
- **error recovery param list build**: used when a program error or checking error occurs to build a parameter list in order to invoke a recovery procedure.

Figure 62. File Control Block (FCB) format

The fields are defined as:

**File pointer**
points to the current element of the file.

**Flags**
set of file flags (16 bits). The flags are:
- **FOPEN** indicates that file is open;
- **FINPUT** the file is open for input (output otherwise);
- **FTEXT** the file is of type TEXT;
- **FEOLN** end-of-line condition is true;
**FOEO** end-of-file condition is true;
**FFIXED** file is fixed block (variable block otherwise);
**FSEQ** sequential file;
**FINTER** interactive file;
**FFEOL** end-of-line condition is true, but not as a result of READLN;
**FSUMR** file is prepared for reading;
**FSUMW** file is prepared for writing;
**FALTIO** alternate I/O system in use.

**Elem len** the length of one element of the file
**Symbolic name** the DDNAME of the file.
**Buf idx** count of the number of bytes from beginning of buffer used.
**Buf end** total length of buffer in bytes.
**Rec len** logical record length of current record.

**Rec end** byte offset from beginning of buffer for the end of the current record.
**Pointer to buffer** address of the beginning of the buffer.
**Pointer to record** address of the current record in the buffer.
**Last FCB** back chain of currently open FCBs.
**Next FCB** forward chain of currently open FCBs.
**Pointer to DCB** address of the OS Data Control Block.
**Pointer to DECB** address of the Data Event Control Block.
**Aux buffer** the address of a buffer that needs to be freed when the file is closed.
**Pointer to exten.** the address of another 64 byte area used to implement special I/O interfaces.
**Current status** status of the file.
Writing an assembler language routine for Pascal/VS is a simple operation provided that a set of conventions are carefully followed. There are two reasons for the need for these conventions:

1. **Pascal/VS parameter passing conventions:** As described in "Parameter Passing" on page 76, Pascal/VS parameters are passed in a variety of ways, depending on their attributes.

2. **The Pascal/VS environment:** This is an arrangement of registers and control blocks used by Pascal/VS to handle storage management and runtime error recovery. (see "Register Usage" on page 73.)

12.1 **WRITING ASSEMBLER ROUTINE WITH MINIMUM INTERFACE**

Writing an assembler routine with the minimum interface requires the least knowledge of the runtime environment. However, such a routine has the following deficiencies:

- It may not call a Pascal/VS routine;
- It must be non-recursive;
- If a program error should occur (such as divide by zero), the

Pascal/VS runtime environment will not recover properly and the results will be unpredictable.

When a Pascal/VS program invokes an assembler language routine, register 14 contains the return address and register 15 contains the starting address of the routine. The routine must follow the System/370 linkage conventions and save the registers that will be modified in the routine. It must also save any floating point register that is altered in the routine.

Upon entry to the routine, register 13 will contain the address of the register save area provided by the caller, and register 1 will point to the first of a list of parameters being passed (if such a list exists). Once the register values are stored in the caller's save area, the save area address (register 13) must be stored in the backchain word in a save area defined by the assembler routine itself. Before returning to the Pascal/VS routine, the registers must be restored to the values that they contained when the assembler routine was invoked.

If you insert your assembler instructions at the point indicated in the skeletal code shown in Figure 63, your assembler routine can be called from a Pascal/VS routine and you need have no knowledge of the Pascal/VS environment.

```assembly
anyname CSECT
ENTRY proname declare routine name as an entry point
proname DS 0H entry point to routine
STM 14,12,12(13) save Pascal/VS registers in Pascal/VS save area
BALR basereg,0 establish base register
USING * ,basereg
ST 13,SAVEAREA+4 store Pascal/VS save area address
LA 13,SAVEAREA load address of local save area

: body of assembler routine

: restore the floating point registers if
: they were saved
L 13,4(13)
LM 14,12,12(13)
BR 14

SAVEAREA DC 20F'0' return to Pascal/VS
END local save area

Figure 63. Minimum interface to an assembler routine: skeletal code to be invoked from Pascal/VS
```
If an assembler routine has at least one of the following characteristics, the general interface must be used:

- It calls a Pascal/VS routine;
- It is recursive;
- Program errors must be intercepted and diagnosed by the Pascal/VS runtime environment.

Two assembler macros are available which are used to generate the prologue and epilogue of an assembler routine with a general Pascal/VS interface. The macro names are PROLOG and EPILOG and their forms are described in the figure above.

The PROLOG macro preserves any registers that are to be modified and allocates storage for the DSA. It also includes code to recover from a stack overflow and program error. The label of the macro is established as an ENTRY point; register 2 is established as the base register for the first 4 kilobytes of code.

Upon entering a routine prior to executing the PROLOG code, the following registers are expected to contain the indicated data:

- Register 1 - address of the parameter list built by the caller, which is 144 bytes into the DSA to be used by the called routine.
- Register 12 - address of the Pascal Communication Work Area (PCWA).
- Register 13 - address of the DSA of the calling routine.
- Register 14 - return address.
- Register 15 - address of the start of the called routine.

Upon executing the code generated by the PROLOG macro, the registers are as follows:

- Register 0 - unchanged
- Register 1 - address of an area of storage in which parameter lists may be built to pass to other routines.
- Register 2 - base register for the first 4 kilobytes of code within the invoked routine.
- Registers 3 through 11 - unchanged.
- Register 12 - unchanged
- Register 13 - address of the local DSA of the routine just invoked. The first 144 bytes is the register save area for the invoked routine. Following the save area is where the parameters passed in by the caller are located. Immediately after the parameters is storage for local variables followed by a parameter list build area.
- Register 14 - unchanged.
- Register 15 - unpredictable.
The EPILOG macro restores the saved registers, then branches back to the calling routine. In order for the epilogue to execute properly, register 13 must have the same contents as was established by the prologue.

The contents of the floating point registers are not saved by the PROLOG macro. If the floating point registers are modified, they must be restored to their original contents prior to returning from the routine.

A skeleton of a general-interface assembler language routine which may be called by a Pascal/V$ program is given below.

```
* The following names have the indicated meaning
* 'csectnam' is the name of the csect in which the routine resides
* 'procname' is the name of the routine.
* 'parmsize' is the length of the passed-in parameters
* 'varsizes' is the storage required for the local variables
* 'lastreg' is the highest register (up to 12) which will be modified
* 'plist' is the length of the largest parameter list required for calls
  * to other routines from "procname"
*
csectnam CSECT
*
procname PROLOG LASTREG=lastreg,VARS=varsizes+parmsize,PARMS=plist
  :  
  :  == insert code here
  : 
*
  EPILOG LASTREG=lastreg
  END
```

Figure 65. General interface to an assembler routine: skeletal code to be invoked from Pascal/V$
12.3 RECEIVING PARAMETERS FROM ROUTINES

Parameters received from a Pascal/VS routine are mapped within a list in the manner described in "Parameter Passing" on page 76. At invocation register 1 contains the address of this list.

If the general interface (see "Writing Assembler Routine with General Interface" on page 84) is used in writing the assembler routine, passed-in parameters start at offset 144 from register 13 after the prologue has been executed.

12.4 CALLING PASCAL/VS ROUTINE FROM ASSEMBLER ROUTINE

An assembler language routine may call a Pascal/VS routine provided that:

1. the Pascal/VS runtime environment is active (this will be so if the assembler routine was invoked by a Pascal/VS procedure),

2. the general Pascal/VS interface was incorporated, and

3. the Pascal/VS routine to be called is an ENTRY routine.

Prior to making the call, register 1 must contain the value assigned to it within the PROLOG code. Parameters to be passed are stored into appropriate displacements from register 1 as described in "Parameter Passing" on page 76.

At the point of call, register 12 must contain the address of the Pascal Communications Work Area (PCWA). This will be the case if the assembler routine was invoked from a Pascal/VS routine and has not modified the register.

To perform the call, a V-type constant address of the routine to be called is loaded into register 15 and then the instruction 'BALR 14,15' is executed.

12.5 SAMPLE ASSEMBLER ROUTINE

In Figure 66 on page 87 and Figure 67 on page 87, a sample assembler routine is listed which may be called from a Pascal/VS program. This routine executes an OS TPUT macro to write a line of text to a user's terminal.
type
  BUFINDEX = 0..80;
  BUFFER = packed array[1..80] of CHAR;

(*this routine is in assembly language*)
procedure TPUT(
  const BUF : BUFFER;
  LEN : BUFINDEX);
EXTERNAL;

(*this routine is called from the assembly language routine*)
procedure ERROR(
  RETCODE: INTEGER;
  const MESSAGE: STRING);
ENTRY;
begin
  WRITELN(OUTPUT, MESSAGE, ',', RETURN CODE = ',', RETCODE)
end;

Figure 66. Pascal/VS description of assembler routine: the assembler routine is shown in Figure 67.

12.6 CALLING A PASCAL/VS MAIN PROGRAM FROM ASSEMBLER ROUTINE

A Pascal/VS program may be invoked from an assembler language routine by loading a V-type address constant of the main program name into register 15 and executing a BALR instruction with 14 as the return register.

Program to be called:

```pascal
program test;
begin
end.
```

Assembler instructions to perform the call under CMS:

```assembly
LA 1,PLIST
L 15,=V(TEST)
BALR 14,15

PLIST DS 0F
DC CL8'TEST'
DC CL8'token 1'
DC CL8'token 2'
...,
DC CL8'token n'
DC 8X'FF'
```

Assembler instructions to perform the call under VS2 (and TSO):

```assembly
LA 1,PLIST
L 15,=V(TEST)
BALR 14,15

PLIST DS 0F
DC XL1'80' set first bit of address
DC AL3(PARMS)
...,
DC FL2'length' length of parameter string
DC C'parm string goes here'
```

Figure 68. Example of calling a Pascal/VS program from an assembler routine.
13.1 PROGRAM INITIALIZATION

Upon invoking a Pascal/VS program, the routine which is responsible for establishing the Pascal/VS execution time environment gains control and performs the following functions:

1. Memory is obtained in which dynamic storage areas (DSA) are allocated and deallocated.
2. The Pascal Communication Work Area (PCWA) is created and initialized.
3. An environment is set up to intercept program interrupts (fixed point overflow, divide by zero, etc.)
4. The main program is called.
5. Upon return from the main program any open files are closed.
6. Acquired memory is freed.
7. Control is returned to the system.

13.2 THE MAIN PROGRAM

The main program is called as an ordinary procedure from the environment setup routine (AMPXSTRT). The external name AMPXBEGN is associated with the address of the main program execution code.

13.3 INPUT/OUTPUT ROUTINES

The I/O operations (which appear as calls to predefined procedures in Pascal/VS) are implemented as calls to internal procedures within the runtime environment.

<table>

</tr>
</tbody>
</table>

13.4 HEAP MANAGEMENT ROUTINES

The NEW operation generates a call to the internal procedure AMPXNEW. This procedure allocates storage within a heap. If a heap has not yet been created, NEW will obtain memory from the operating system to create a heap.

The DISPOSE operation generates a call to the procedure AMPXDISP. This procedure deallocates the heap storage acquired by a preceding call to AMPXNEW.

The MARK operation generates a call to the procedure AMPXMARK. This procedure creates a new heap from which subsequent calls to AMPXNEW will obtain storage.

The RELEASE operation generates a call to the procedure AMPXRSEL. This procedure frees a heap that was previously created via the AMPXMARK procedure.
Subsequent calls to AMPXNEW will obtain storage from the heap which was active prior to the call of AMPXMARK.
Release 1.0 of Pascal/VS has several differences from 'standard' Pascal. Most of the deviations are in the form of extensions to Pascal in those areas where Pascal does not have suitable facilities.

14.1 PASCAL/VS RESTRICTIONS

Pascal/VS contains the following restrictions that are not in standard Pascal.

Non-local labels
Branching to a non-local label (by means of the goto statement) is not supported.

Files
Fields within records and elements of arrays may not be declared as files. Files may not be pointer qualified.

Routine parameters
A routine which is passed as a parameter must not be nested within another routine; that is, it must be at the outermost nesting level.

14.2 MODIFIED FEATURES

Pascal/VS has modified the meaning of a negative length field qualifier on an operand within the WRITE statement.

14.3 NEW FEATURES

Pascal/VS provides a number of extensions to Pascal.

- The keyword "range" may be prefixed to a subrange type definition to permit the lower value to be a constant expression.
- A varying length character string is provided. It is called STRING.
- The STRING operators and functions are concatenate, LENGTH, STR, SUBSTR, DELETE, TRIM, LTRIM, COMPRESSION and INDEX.
- The parameters of the text READ procedure may be length-qualified.
- Calls to FORTRAN subroutines and functions are provided for.
- Input files may be opened as "INTERACTIVE" so that I/O may be done conveniently from a terminal.
- I/O is supported for partitioned data sets.
- Files may be explicitly closed by means of the CLOSE procedure.
- The DDNAME to be associated with a file may be determined at execution time with the OPEN procedure.
- The space structure is provided for processing packed data.
- Records may be packed to the byte.
- The tagfield in the variant part of a record may be anywhere within the fixed part of the record.
- Fields of a record may be named.
- Tag specifications on record variants may be ranges (x..y).
- Integers may be declared to occupy bytes and halfwords in addition to full words, as a result of the packed qualifier.
- Sets permit the operations of set complement and set exclusive union.
- A function may return any type of data except a file.
- The operators '+', '*', '*' and '-' may be applied to data of type integer. When applied to integers, the operators act on a bit by bit basis. Shift operations on data are also provided.
- Integer constants may be expressed in hexadecimal digits.
- Real constants (floating point) may be expressed in hexadecimal digits.
- String constants may be expressed in hexadecimal digits.
- The %INCLUDE facility provides a means to include source code from a library.
- A parameter passing mechanism (const) has been defined which guarantees that the actual parameter is not modified yet does not require the copy overhead of a pass by value mechanism.
- **leave, continue** and **return** are new statements that permit a branching capability without using a goto.
- Labels may be either a numeric value or an identifier.
- **case** statements may have a range notation on the component statements.
- An otherwise clause is provided for the **case** statement.
- The variant labels in records may be written with a range notation.
- The assert statement permits runtime checks to be compiled into the program.
- The following system interface procedures are supported: **HALT, CLOCK, and DATETIME.**
- Constants may be of a structured type (namely arrays and records).
- To control the compiler listing, the following listing directives are supported: **%PAGE, %SKIP, and %TITLE.**
15.1 SYSTEM DESCRIPTION

The Pascal/VS compiler runs on the IBM System/370 to produce object code for the same system. System/370 includes all models of the 370, 303x, and 43xx computers providing one of the following operating environments:

- VM/CMS
- OS/VS2 TSO
- OS/VS2 Batch

15.2 MEMORY REQUIREMENTS

Under CMS, Pascal/VS requires a virtual machine of at least 768K to compile a program. Execution of a compiled program can be performed in a 256K CMS machine.

The compiler requires a minimum region size of 512K under VS2 (MVS). A compiled and link-edited program can execute in a 128K region.

15.3 IMPLEMENTATION RESTRICTIONS AND DEPENDENCIES

Boolean expressions

Pascal/VS "short circuits" boolean expressions involving the and and or operators. For example, given that A and B are boolean expressions and X is a boolean variable, the evaluation of

\[ X := A \text{ or } B \text{ or } C \]

would be performed as

if A then
  X := TRUE
else
  if B then
    X := TRUE
  else
    X := C

The evaluation of

\[ X := A \text{ and } B \text{ and } C \]

would be performed as

if \(-A\) then
  X := FALSE
else
  if \(-B\) then
    X := FALSE
  else
    X := C

See the section entitled "Boolean Expressions" in the Pascal/VS Reference Manual for more details.

Floating-point

Some commonly required characteristics of System/370 floating-point arithmetic are shown in Figure 69 on page 94.

Identifiers

Pascal/VS permits identifiers of up to 16 characters in length. If the compiler encounters a longer name, it will ignore that portion of the name longer than 16 characters.

Names of external variables and external routines must be unique within the first 8 characters. Such names may not contain an underscore '_' within the first 8 characters.

Integers

The largest integer that may be represented is 2147483647.9 This is the value of the predefined constant MAXINT.

The most negative integer that may be represented is \(-2147483648\). This is the value of the predefined constant MININT.

Routine nesting

Routines may be nested up to eight levels deep.

Routines passed as parameters

The following standard routines may not be passed as parameters to another routine:

ABS, CHR, CLOSE, DISPOSE, EOF, EOLN, FLOAT, GET, HBOUND, HIGHEST, INTERACTIVE, LBOUND, LENGTH, LOWEST, MARK, MAX, NEW, ODD, ORD, PACK, PAGE, PRED, PUT, READ, READLN, RELEASE, REWRITE, ROUND, SIZEOF, SQR, STR, SUC, TRUNC, UNPACK, WRITE, WRITELN

A routine may not be passed as a parameter if it is nested within another routine; that is, a rou-

---

9 This is the highest signed value that may be represented in a 32 bit word.
<table>
<thead>

<td>'7FFFFFFF0000000000'XR</td>
</tr>
<tr>
<td>Minreal³</td>
<td>5.39760534693403E-79</td>
<td>'0000000000000000000'XR</td>
</tr>
<tr>
<td>Epsilon⁴</td>
<td>1.38777878078145E-17</td>
<td>'3300000000000000000'XR</td>
</tr>
</tbody>
</table>

¹ The syntax '...'XR is the way hexadecimal floating-point numbers are represented in Pascal/VS. See the section entitled "Constants" in the Pascal/VS Reference Manual.

² Maxreal is the largest finite floating-point number that may be represented.

³ Minreal is the smallest positive finite floating-point number that may be represented.

⁴ Epsilon is the smallest positive floating-point number such that the following condition holds:

\[ 1.0 + \text{epsilon} > 1.0 \]

This value is often needed in numerical computations involving converging series.

---

**Figure 69.** Characteristics of System/370 floating point arithmetic

- A FORTRAN function or subroutine may not be passed as a parameter to a Pascal/VS routine.

- Given a set type of the form

\[ \text{set of a..b} \]

where "a" and "b" express the lower and upper bounds of the base scalar type, the following conditions must hold:

- \( \text{ORD}(a) \geq 0 \)
- \( \text{ORD}(b) \leq 255 \)
### 16.1 PASCAL/VS COMPILER MESSAGES

<table>

</tbody>
</table>

**Procedure/Function previously FORWARDed**

The indicated routine declaration that contains the FORWARD directive was already previously forwarded.

**Additional errors not printed**

The indicated construct contained more errors, but were not printed due to space considerations.

**Illegal hexadecimal or binary digit**

An invalid hexadecimal digit was detected within a hexadecimal constant specification of the form

'...X, '...XC, or '...XR;

or, an invalid binary digit was detected within a binary constant specification of the form

'...B.

The following characters are valid hexadecimal digits:

0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F,
a, b, c, d, e, f

The following characters are valid binary digits:

0, 1

**Unidentifiable character**

The indicated character is not recognized as a valid token.

**Digit expected**

A decimal digit was expected but missing at the indicated location.

**Real constant has too many digits**

The indicated floating point constant contains more digits than the compiler allows for in scanning. If this error should occur, please notify the compiler maintenance group at IBM.

**Integer constant too large**

The indicated integer constant is not within the range -2147483648 to 2147483647.

**End of string not seen**

A string constant may not cross a line boundary. This error is often the result of mismatched quotes.

If a string constant is too large to fit on one line, it must be broken up into multiple strings and concatenated with the || operator. (Concatenation of string constants is performed at compile time).

**Hexadecimal integer constant may not exceed 8 digits**

The indicated hexadecimal constant exceeds the maximum allowed number of digits.

**Char string is too large**

The indicated string constant exceeds 255 characters, which is the implementation limit. This may happen when multiple string constants are concatenated.
### Standard routines not permitted as parameters

Standard routines which generate in line code may not be passed as parameters to other routines. The following is a list of such routines:

- ABS, CHR, CLOSE, DISPOSE, EOF, EOLN, FLOAT, GET, HBOUND, HIGHEST, INTERACTIVE, LBOUND, LENGTH, LOWEST, MARK, MAX, NEW, ODD, ORD, PACK, PAGE, PRED, PUT, READ, READLN, RELEASE, RESET, REWRITE, ROUND, SIZEOF, SQR, STR, SUCC, TRUNC, UNPACK, WRITE, WRITELN

### Variable must be of type file

The indicated variable is required to be of a file type.

### Must be of type TEXT

The indicated variable is required to have been declared with the predefined type TEXT.

### Required parameters are missing

The indicated READ or WRITE statement contains no parameter from which to reference data.

### Comma ',' expected

### User defined scalars not permitted

Expressions which are of a user defined enumerated type may not be directly read from or written to a text file.

### Operand of READ/WRITE not of a valid type

Any parameter passed to the procedures READ or WRITE (text file case) must be compatible with one of the following types:

- INTEGER
- REAL
- CHAR
- BOOLEAN
- STRING
- packed array[1..n] of CHAR
  where n is a positive integer constant.

### Length field must be integer

The indicated length qualifier expression in a READ or WRITE statement is not of type integer. Any length specification within a text-file READ/WRITE must be of type integer.

### Set contains constant member(s) which are out of range

The indicated set constant contains members which are not valid for the set variable to which the constant is being assigned. For example,

```pascal
var S : set of 10..20;
begin
  S := [1,2]; (* <= this statement would produce error 45*
end;
```

This error may also occur when a set constant is being passed as a parameter.

### 2nd length applicable only to REAL data

In the procedure WRITE (text file case), only expressions of type REAL are permitted to have two length field qualifications.

</table>
| 62   | Type specification expected  
At the place indicated, a type definition is expected but is missing. |
| 63   | '...' expected |
| 64   | Expression's type is incorrect or incompatible within context  
This error is caused by a number of reasons:  
- A unary or binary operator is being applied to an expression which is of a type that is not valid for the operator.  
- Two expressions being joined by a binary operator are of incompatible types.  
- The parameters of the MIN/MAX functions are not of consistent types.  
- Members of a set constructor have inconsistent types. |
| 65   | Subrange lower bound > upper bound |
| 66   | Assignment to ptr qualified variant record invalid  
The indicated statement attempts to assign to the whole of a pointer qualified record with variant fields. Such an assignment is not valid under Pascal/VS. This restriction is necessary because the pointer qualified record may have been allocated with a size that is specific to its active variant.  
Example of violation:  
```pascal  
type  
R = record  
case BOOLEAN of  
TRUE: (C:CHAR);  
FALSE: (A: ALPHA)  
end;  
var P : -&gt;R;  
RR : R;  
begin  
NEW(P,TRUE);  
P-&gt; := RR  (*&lt;==invalid assignment*)  
end  
``` |
| 67   | Real type not valid here  
The indicated expression is of type REAL. An expression of this type is not valid within the associated context. |
| 68   | "OF" expected |
| 69   | Tag constant does not match tag field type  
Within a record definition, a variant tag is being defined which is of a type that is not compatible with the corresponding tag field type.  
Within a call to NEW or SIZEOF, a tag value is specified which is of a type that is not compatible with the corresponding tag field type of an associated record variable. |
| 70   | Duplicate variant field  
Within a record definition, a variant tag is being defined more than once. |

</tbody>
</table>

For more details on each error code, refer to the Pascal/VS Programmer's Guide.
| 164 | **Unrecognizable procedure/function directive**  
The indicated identifier was interpreted as a procedure or function directive but was not recognizable. The following are the only recognizable directives:  
- FORWARD  
- EXTERNAL  
- FORTRAN  
- ENTRY |
| 165 | **FORTRAN subroutines may not be passed as parameters**  
Only Pascal/V5 routines may be passed as parameters; FORTRAN subroutines may not.  
One way to get around this problem is to define a Pascal/V5 procedure which does nothing more than call the FORTRAN subroutine. The Pascal/V5 procedure would then be passed in place of the FORTRAN subroutine. |
| 166 | **FORTRAN subroutine parameters may not be passed by value**  
All formal parameters of a FORTRAN subroutine must be passed by reference: either by VAR or by CONST. |
| 167 | **FORTRAN functions may return only scalar values**  
A FORTRAN function may only return values that are scalars (including floating point). |
| 168 | **%INCLUDE member not found in library**  
The library member which was to be included into the source program could not be found. |
| 169 | **Floating point computational error**  
The indicated floating point expression causes a program error when evaluated. |
| 170 | **Data storage exceeds addressability of machine**  
The memory required to contain all declared variables within a routine or main program exceeds the capacity of the computer; that is, it exceeds 16 megabytes. |
| 171 | **Only STATIC/DEF variables may be initialized**  
The only class of variables which may be initialized at compile time are DEF and static variables. |
| 172 | **Variable's address is not compile-time computable**  
The indicated value assignment could not be performed. In order for a variable to be initialized at compile-time, its address must be compile-time computable. |
| 173 | **Array structure has too many elements**  
The indicated array structure contains more elements than was declared for the array type. |
| 174 | **Repetition factor applicable to constants only**  
Within a array structure, only a constant may be qualified with a repetition factor; a general expression may not. |
| 175 | **No corresponding record field**  
The indicated record structure contains more elements than there are fields within the record type. |
| 176 | This identifier is a reserved name |
|     | An attempt was made to declare an identifier which is a reserved name. |
| 177 | Numeric labels must lie within the range 0..9999. |
| 178 | Identifier was previously referenced illegally |
|     | The indicated identifier that was just declared was referenced previously within the associated routine. Pascal/VS requires an identifier to be declared prior to its use. |
| 179 | Recursive reference within constant declaration |
|     | A constant declaration of one of the following forms was detected: |
|     | `const X = X;` or |
|     | `const X = "some expression involving X"` |
|     | Such recursion within a constant declaration is not permitted. |
| 180 | Repetition factor not applicable to record structures |
|     | The indicated record structure contains a component which is qualified with a repetition factor. Only array structures are permitted to have repetition factors. |
| 181 | Label previously referenced from a GOTO invalidly |
|     | The indicated label was previously referenced in a goto statement that is not a constituent of the statement sequence in which the label is defined. |
|     | Example |
|     | ```
|     | begin |
|     |    goto LABEL1; |
|     |    for I := 1 to 10 do |
|     |       begin |
|     |          LABEL1: A[I] := 0; (*<<<label was previously referenced invalidly*) |
|     |       end; |
|     | end |
| 182 | A GOTO may not reference a label within a separate stmt sequence |
|     | The indicated goto statement references a label which was previously defined within a statement sequence of which the goto is not a constituent. Such a reference is not permitted. |
|     | Example |
|     | ```
|     | begin |
|     |    for I := 1 to 10 do |
|     |       begin |
|     |          LABEL1: A[I] := 0; |
|     |          ... |
|     |       end; |
|     |    goto LABEL1; (*<<<invalid reference of label *) |
|     | end ```
### CASE label outside range of indexing expression

The indicated case label within a case statement has a value which is outside the range of the indexing expression. For example,

```pascal
var I: 0..10;
begin
    case I*2 of (*range of index is 0..20 *)
        0: ...;
        1..20: ...
        30: ... (*<== this label is out of range of index*)
    end
end
```

### Second operand of MOD operation must be positive integer

The indicated expression involving the mod operator was found to be invalid; the second operand is required to be a positive integer.

### Identifier used in type definition at line nnn is out of context: xxxx

The identifier 'xxxx' appeared in a pointer type definition of the form '->xxxx' at line 'nnn', but the identifier was subsequently declared as something other than a type.

Example:

```pascal
type X = ->Y;
var Y: INTEGER; (*<== would cause error 600 to be generated *)
```

### Type identifier referenced at line nnn is undeclared: xxxx

The identifier 'xxxx' appeared in a pointer type definition of the form '->xxxx' at line 'nnn', but the identifier was not subsequently declared.

### Label xxxx was declared and/or referenced but was not defined

The label named 'xxxx' was declared and/or referenced from within the associated routine, but was not ever defined.

### procedure/function xxxx was forwarded but not resolved

The procedure or function named 'xxxx' was declared with the directive 'FORWARD', but the body of the routine was not subsequently declared.
## 16.2 INPUT/OUTPUT MESSAGES

<td>The maximum number of MACLIBS that may be specified when invoking the PASCALVS EXEC is eight.</td>
</tr>
</tbody>
</table>
• "Command Syntax Notation" on page 117
• "Installation Instructions" on page 119
The syntax notation used to illustrate TSO commands is explained in the manual TSO Command Language Reference (GC28-0646). The notation used to illustrate CMS commands is explained in the manual VM/370: CMS Command and Macro Reference (GC20-1818).

Briefly, the conventions used by both notations are as follows.

- Items in brackets [ ] are optional. If more than one item appears in brackets, then no more than one of them may be specified; they are mutually exclusive.
- Items in capital letters are keywords. The command name and keywords must be spelled as shown.
- Items in lowercase letters must be replaced by appropriate names or values.
- Items which are underlined represent defaults.
- The special characters ' ( ) * must be included where shown.
This section describes how to install Pascal/VS under OS/VS2 and CMS-VM/370 from the distribution tape.

All VS2 partitioned data sets (other than the compiler source) were stored on the tape by using the IEBCOPY utility program. VS2 sequential data sets were stored by using the IEBGENER utility program.

The CMS version of the package is located at file 14 on the tape. It was stored by using the TAPE DUMP command.

The source of the compiler was stored using the utility program IEBUPDTE.

The files on the distribution tape contain the following data sets.

**File 1:** INSTALL.CNTL
A sample of the job control language (JCL) required to install Pascal/VS under OS/VS2 (MVS).

**File 2:** LOADSRC.CNTL
A sample of the job control language (JCL) required to load the Pascal/VS source from the distribution tape.

**File 3:** PASCALVS CONTENTS
A sequential data set which lists the contents of the Pascal/VS package.

**File 4:** PASCALVS LINKLIB
A partitioned data set which contains the modules of the compiler.

**File 5:** PASCALVS LOAD
A partitioned data set which contains the Pascal/VS run time library.

**File 6:** PASDEBUG LOAD
A partitioned data set which contains the Pascal/VS debug library.

**File 7:** PASCALVS MACLIB
The standard include library.

**File 8:** PASCALVS CLIST
A partitioned data set containing two clists: PASCALVS and PASMOD.

**File 9:** PASCALVS PROCLIB
A partitioned data set which contains the JCL cataloged procedures for running the compiler as a batch job under MVS.

**File 10:** MASTER MENUS
A partitioned data set which contains SPF menus which will permit Pascal/VS to be invoked from the program product SPF.

**File 11:** MASTER PROCS
A partitioned data set which contains the command procedures necessary to invoke Pascal/VS under the program product SPF.

**File 12:** PASCALVS MESSAGES
A sequential data set which contains the compiler messages.

**File 13:** SAMPLE PASCAL
A sample Pascal/VS program.

**File 14:** CMS dump of the entire Pascal/VS package:
- PASCALVS CONTENTS
  A listing of the contents of the Pascal/VS package.
- PASCALVS MODULE
  The first pass of the compiler.
- PASCALVS MODULE
  The second pass of the compiler.
- PASCALVS TXTLIB
  The Pascal/VS run time library.
- PASDEBUG TXTLIB
  The Pascal/VS debug library.
- PASCALVS MACLIB
  The standard INCLUDE library.
- PASCALVS EXEC
  CMS EXEC which invokes the compiler
- PASCAL1 EXEC
  an internal EXEC invoked from PASCALVS EXEC.
- PASCAL2 EXEC
  an internal EXEC invoked from PASCALVS EXEC.
- PASC1MOD EXEC
  CMS EXEC which creates a load module from a compiled Pascal/VS program.
- PASCALVS MESSAGES
  List of the compiler messages.
- LOADSRC EXEC
  An EXEC which will load the source of the compiler from the tape.
- SAMPLE PASCAL
  A sample program.

**File 15:** PASCAL PASCAL

Installation Instructions 119
The source of the first pass of the compiler.

File 16: PASCALT.PASCAL
The source of the second pass of the compiler.

File 17: PASCALD.PASCAL
The source of the interactive debugger.

File 18: PASCALX.PASCAL
The source of the runtime library routines.

File 19: PASCALX.ASM
The source of the operating system interface routines.

File 20: MACLIBL.PASCAL
Include library for first pass of the compiler.

File 21: MACLIBT.PASCAL
Include library for second pass of the compiler.

File 22: MACLIBD.PASCAL
Include library for interactive debugger.

File 23: MACLIBX.PASCAL
Include library for runtime routines.

B.1 INSTALLING PASCAL/VS UNDER CMS

To install Pascal/VS under CMS perform the following:

1. Have the distribution tape mounted at address 181.

2. Link to the mini-disk (in write mode) where the compiler is to be stored. This is done with the CP LINK command. The mini-disk must have at least 1210 blocks of free storage\(^{10}\).

3. Access this disk with the ACCESS command.

4. Execute the following two commands:

   ```
   TAPE FSF 13
   TAPE LOAD * * m
   ```

   where "m" is the single letter file mode of the disk that was accessed in the previous step.

---

\(^{10}\) 800 byte blocks are assumed. This amount is equivalent to 5 cylinders on a 3330 disk.
B.2 INSTALLING PASCAL/VS UNDER VS2

This section explains how to install Pascal/VS under an OS/VS2 system.

B.2.1 Loading Files from Distribution Tape

A sample of the job control language required to install Pascal/VS under VS2 (MVS) is stored as the first file of the distribution tape. To retrieve this data set, the utility program IEBGENER must be used. The JCL shown in Figure 70 may serve as a model job to retrieve this file. DD operands which are highlighted will require modification to suit your installation requirements. The serial number of the distribution tape must be placed where the name "TAPEVOL" appears in the DD statement named SYSUT1.

The data set name (DSN=) in the DD card named SYSUT2 is arbitrary. It is the name of the data set where the first file on the tape is to be stored. The appropriate UNIT and volume serial number for disk storage must be specified for DD SYSUT2.

Figure 71 on page 122, Figure 72 on page 123, and Figure 73 on page 124 contain a listing of the first file of the distribution tape. The following modifications are required prior to submitting this job.

- The name "TAPEVOL" must be replaced with the volume serial number of the distribution tape in the DD statement named SYSUT1 in job step STEP1.
- The UNIT specification for tapes has been given the generic name of "TAPE"; this should be changed to the appropriate generic at your installation.
- The UNIT specification for disk storage has been specified as "3330"; this should be changed to the appropriate specification at your installation.
- The disk volume on which Pascal/VS is to be installed must be specified where indicated ("DISKOUT") in the following DD statements:
  - in STEP1: SYSUT2
  - in STEP2: SYSUT2
  - in STEP3: D54, D55, D56,
  - D57, D58, D59,
  - D510, D511
  - in STEP4: SYSUT2
  - in STEP5: SYSUT2
- The DD statements named SYSUT3 and SYSUT4 in job step STEP3 represent temporary work storage. The generic name "SYSDA" is used as a UNIT specification; this should be changed to the appropriate generic at your installation.
- The tape density is specified within the DEN suboperand of the DCB attributes. In the sample job, DEN is set to 3 which indicates a tape density of 1600 BPI. If your distribution tape is at some other density, then the DEN operands should be changed accordingly.
- The high level qualifier of data set names that are to be cataloged should be modified to follow installation conventions. (The examples in this manual assume a high level qualifier of "SYS1".)

Figure 71. Sample installation job: (continued in Figure 72 on page 123)
Figure 72. Sample installation job: (continued in Figure 73 on page 124)
B.2.2 The TSO CLists

Distributed with the compiler are two CLISTs: PASCALVS and PASCMOD. These CLISTs reside in the partitioned data set PASCALVS.CLIST (file 8 of the distribution tape).

These CLISTs should be stored in a public CLIST library that is accessible to TSO users through DDname SYSPROC.

Each CLIST must be modified so that the correct high level qualifier name is used to reference the Pascal/VS data sets. In PASCALVS, the symbol named "FIRSTNAME" should be set to the appropriate name. In PASCMOD, the symbols named "LIBRARY" and "DEBUGLIB" should be set to the names of the Pascal/VS run time library and the debug library, respectively.

B.2.3 Cataloged Procedures

Distributed with the compiler are four cataloged procedures for invoking the compiler from a batch job: PASC, PASCCG, PASCL, and PASCCCL. These procedures reside in the partitioned data set PASCALVS.PROCLIB (file 9 of the distribution tape).

These procedures should be stored in a cataloged procedure library, so that the names will be recognized when referenced from a batch job.

Each procedure must be customized to reflect the data set naming convention chosen at your installation. For a listing of the cataloged procedures see "IBM Supplied Cataloged Procedures" on page 21.

B.2.4 SPF Menus and Procedures

If your TSO installation utilizes the Structured Programming Facility (SPF) (program number 5740-XT8), you may invoke the Pascal/VS compiler from SPF by means of the foreground/background menus.

File 11 on the distribution tape is a partitioned data set which contains the SPF menus required to add Pascal/VS to the list of compilers which may be invoked in the foreground/background menu of SPF. Each member in this data set should be copied into the partitioned data set named

"SPF22.MASTER.MENUS"

11 At some installations this data set may be named "SPF22.MOD1.MENUS".
The following members of this data set will be replaced:  

- FORA
- JOBBA
- JOBB

All other members will be new.

File 11 of the tape is a partitioned data set which contains the foreground and background procedures for invoking the compiler. Each member of this data set should be placed in the data set named:

"SPF22.MASTER.PROCS"

The primary option menu of SPF is the member named APIOPI in SPF22.MASTER.MENUS. This menu should be modified so that the selection "5.9" will activate the Pascal/VS foreground menu, and the selection "4.7" will activate the Pascal/VS background menu. For information on installing and customizing SPF refer to the manual TSO 3270 Display Support and Structured Programming Facility Version 2.2: Installation and Customization Guide(SH20-2402).  

R.3 LOADING THE SOURCE UNDER CMS  

The compiler source is stored on the distribution tape beginning at file 15; that is, 14 tape marks from the beginning of the tape. It consists of nine tape files stored in the IEBUPDTE format. To read such a format under CMS, the TAPPDS command must be utilized.

The LOADSRC EXEC, which is provided as part of the Pascal/VS package, may be used to load all of the source files to a single disk. To run this EXEC, perform the following:

1. Have the distribution tape mounted at address 181.
2. Access the disk where the source files are to be stored in R/W mode. The disk must have the equivalent of 45 free cylinders of 3330 storage.
3. Make sure that there is the equivalent of at least 2 free cylinders of 3330 storage on your "A" disk.

4. Invoke the LOADSRC EXEC as follows:

   LOADSRC fm

   where "fm" is the single letter file mode of the disk to where the source files are to be placed. The EXEC will print out messages as it processes the tape.

R.4 LOADING THE SOURCE UNDER VS

The compiler source is stored on the distribution tape beginning at file 15. It consists of nine tape files stored in the IEBUPDTE format.

File 2 of the distribution tape contains the JCL which copies the source files to disk storage. This file is unloaded when the compiler is installed and has been given the name "LOADSRC.CNTL".

Prior to submitting the job, it must be customized as follows:

- In ddname SYSIN of jobstep STEPL, the volume serial number of the distribution tape should be placed where the name TAPEVOL is shown.
- The UNIT specification for tapes has been given the generic name "TAPE"; this should be changed to the appropriate generic at your installation.
- The UNIT specification for disk storage has been specified as "3330"; this should be changed to the appropriate specification at your installation.
- The disk volume on which the source files are to be stored must replace the name "DISKVOL" in the DD statement named SYSUT2 in each job step.
- The high level qualifier for the data set names to be cataloged is arbitrary. In the supplied JCL, the name "SOURCE" is used.
- The tape density is specified within the DEN suboperand of the DCB attributes. In the JCL, DEN is set to 3 which indicates a tape density of 1600 BPI. If your distribution tape is at some other density, then the DEN operands should be changed accordingly.

---

12 As a precautionary measure, we suggest that you rename the members FORA, JOBBA, and JOBB prior to replacing them with the new copy.
13 You should look at the names of each member that we are supplying to make sure that they do not conflict with any previously existing member.
14 At some installations this data set may be named "SPF22.MODL.PROCS".
15 This is roughly 15000 800-byte blocks. Once the source files have been installed, you may find it desirable to pack them in order to save disk storage.
Figure 74. Listing of the JCL to copy source files from tape: this job is stored as file 2 of the distribution tape. (continued in Figure 75 on page 127).
