## ATTENTION USERS OF THE NORTH STAR ZPB-2A PROCESSOR BOARD

### WRITE DATA RACE CONDITION

A race condition exists in the write data logic of the ZPB-2A CPU board which can interfere with the operation of other boards on the S-100 bus if these boards utilize an internal bi-directional data bus. The following modification will alleviate this problem without degrading the performance of the North Star CPU or any other known device sharing the bus.

Locate IC 7F. It is a 74LS132 in the upper left section of the ZPB circuit board. Remove this chip from its socket, bend out pin 10 and replace the IC in its socket in such a way that pin 10 sticks out without making contact with its assigned socket hole or with any other component. Make sure that the chip is oriented correctly when it is replaced. Pin 10 should be pointing toward the top of the board. This completes the modification.

## User's Manual

### DISK JOCKEY 2/D<sup>tm</sup>

#### INTRODUCTION

The Thinker Toys DISK JOCKEY 2/D (DJ) board features three distinct subsections:

1. A floppy disk controller, capable of reading and writing data in either single density FM code or double density MFM code with write precompensation, which can be connected to any floppy disk drive plug compatible with the Shugart 800/850.
2. A baud rate selectable hardware UART serial interface that allows communication with a terminal device at TTY 20ma current loop or RS-232 levels.
3. Automatic address generation upon reset or power-up which allows a "jump start" to the boot strap program in the ROM contained on the board.

The DJ plugs into an S-100 bus slot in a system with an 8080, 8085, or Z80 (1.7MHz - 5MHz) CPU. The controller has a cable connector for attaching a flat cable to the first floppy disk drive, and can control a chain of up to four drives daisy chained on this cable. A second connector on the DJ is provided for attaching a terminal device.

The DJ uses memory mapped I/O. Device registers used to input from and output to the floppy disk and the serial port are accessed from the CPU board of the S-100 system by references to memory addresses. Some registers differ in function depending on whether they are being read or written.

Most users will not wish to use the hardware level registers directly. Instead, they can call standard disk and serial I/O subroutines contained in 1016 bytes of PROM memory on the DJ board. This PROM occupies a 1024 byte block of S-100 bus memory address space. A 1024 byte RAM is also provided which is used by the PROM firmware for the storage of various disk related variables such as the current track number, the current drive number, etc. An exact map of these variables is included at the end of the PROM listings. The remainder of the RAM may be used as a disk data buffer or for general purpose memory.

The actual addresses where the I/O registers, PROM, and RAM

## Introduction

appear are controlled by another PROM, referred to as the address selection PROM. The PROM is supplied with standard addresses burned into it for these registers. If the standard addresses would conflict with some other device on the system bus, a PROM burned with non-standard addresses can be substituted.

The DISK JOCKEY 2/D uses 2048 bytes of memory starting at 340:000 or E000H (standard version). The first 1016 bytes are occupied by PROM, the next 8 bytes constitute the memory mapped I/O, and the last 1024 bytes contain the RAM buffer.

## PROGRAMMING SPECIFICATIONS

### ROM JUMP TABLE

Most users will wish to take advantage of the standard I/O subroutines supplied in PROM on the DJ.

The user should branch to the appropriate address in a jump table in the first few words of the system ROM. Since each subroutine ends with a RET instruction, a CALL instruction should be used to branch to the subroutine.

The jump table contains jump instructions to the true address of the utility routines within the ROM. Having a jump table allows the individual routines to be updated and moved around within the ROM without having to change software that calls the routines. Let A represent the address of word 0 of the onboard ROM. In boards with standard address decoding PROMS, A = 340:000Q (E000H). The address to call for the utility routines are then:

| ADDRESS | STANDARD VALUE |      | SYMBOLIC VALUE | FUNCTION                     |
|---------|----------------|------|----------------|------------------------------|
|         | Octal          | Hex  |                |                              |
| A       | 340:000        | E000 | DBOOT          | DOS bootstrap routine        |
| A+3     | 340:003        | E003 | TERMIN         | Serial input                 |
| A+6     | 340:006        | E006 | TRMOUT         | Serial output                |
| A+9     | 340:011        | E009 | TKZERO         | Recalibrate (seek to TRK0)   |
| A+12    | 340:014        | E00C | TRKSET         | Seek                         |
| A+15    | 340:017        | E00F | SETSEC         | Select sector                |
| A+18    | 340:022        | E012 | SETDMA         | Set DMA address              |
| A+21    | 340:025        | E015 | DREAD          | Read a sector of disk data   |
| A+24    | 340:030        | E018 | DWRITE         | Write a sector of disk data  |
| A+27    | 340:033        | E01B | SELDRV         | Select a disk drive          |
| A+30    | 340:036        | E01E | TPANIC         | Test for panic character     |
| A+33    | 340:041        | E021 | TSTAT          | Serial status input          |
| A+36    | 340:044        | E024 | DMAST          | Read current DMA address     |
| A+39    | 340:047        | E027 | STATUS         | Disk status input            |
| A+42    | 340:052        | E02A | DSKERR         | Loop to strobe error LED     |
| A+45    | 340:055        | E02D | SETDEN         | Set density                  |
| A+48    | 340:060        | E030 | SETSID         | Set side for 2-headed drives |

The specific function of each subroutine is described below.

The subroutine upon completion will execute a RET instruction. A disk subroutine that completes normally will return with the carry flag cleared to zero. A disk subroutine that detects an error condition will return with the carry flag set to 1. A program should always test the carry flag after a return from a disk utility subroutine and branch to an appropriate error handling routine if the carry flag is set.

## Programming Specifications - Serial I/O

### SERIAL I/O

There is a hardware UART on the DJ board along with a crystal controlled baud rate generator. There are sixteen different baud rates available including 12 of the most common. The baud rate of the UART must match the baud rate of the terminal connected to the DJ board in order for the serial interface to function properly.

The UART (Universal Asynchronous Receiver-Transmitter) consists of two independent sections: a transmitter section and a receiver section. Each section has two registers. In the transmitter section one register is loaded by the system bus. The contents of this bus register are transferred to a shift register where start, stop, and (conditionally) parity bits are appended. The transmitted serial data originates from this shift register. Whenever the contents of the system bus register have been transferred to the second shift register the UART sets the TBRE (Transmitter Buffer Register Empty) bit in its status register.

In the receiver section there is a shift register which assembles a parallel data word from the input serial stream after start and stop bits have been removed. When a complete data word has been assembled in this register it is loaded into a second register that is accessible from the system bus. Whenever this bus register is loaded from the receiver shift register the UART sets the DR (Data Ready) bit in its status register.

The subroutine TERMIN can be called to wait for the UART to raise the DR bit of its status register. The character is then transferred to the A register and trimmed to seven bits. Reading the UART's data register automatically resets the DR bit. The TERMIN subroutine will not return until a character arrives.

The subroutine TRMOUT causes the UART to transmit the data in the C register of the CPU. The TBRE bit of the UART's status register is tested. When TBRE is high, the contents of the C register is transferred to the UART's system bus register. This automatically resets the TBRE bit. The TRMOUT subroutine will wait for the TBRE bit to be high before transferring data to the UART.

The subroutine TPANIC can be called to detect the presence of a panic character in the serial input stream. TPANIC tests the DR bit of the UART's status register. When this bit is high, TPANIC calls the TERMIN subroutine and then compares the data from the UART with the contents of the C register. The ZERO flag of the CPU's FLAGS register is set upon completion of the TPANIC subroutine if the character in the C register has been struck on the terminal keyboard.

The subroutine TSTAT can be called to test the condition of

## Programming Specifications - Serial I/O

the DR bit in the UART's status register. Upon completion, the ZERO flag of the CPU's FLAGS register is set if the DR bit is high. The subroutine does NOT reset the DR bit.

### DISK I/O

To understand the significance of the disk utility subroutines, it is necessary to say a few words about how data is organized on the disk.

Information on the disk is organized into 77 concentric tracks. The disk read/write head can be moved to any track by a series of step in or step out commands. A step in command moves the read/write head one track towards the center of the disk. A step out command moves the head one track away from the center of the disk. The numbering of the tracks is arranged so that track zero is the farthest from the center of the disk. One of the responsibilities of the Western Digital 1791 controller is to know the current track number over which the read/write head is located and to calculate how many step in or step out commands are necessary to move the head to a desired new track.

Once the read/write head has been moved to the desired track, the rotation of the disk will move a circle of magnetic material beneath the head. Within this circle of material, data is recorded in distinct regions called sectors. The sector is the smallest amount of information that can be separately read from or written to the disk. There are three different sector formats that IBM currently supports. The table below details the relationship between the size of a sector and the number of sectors that can fit on a single track.

bytes of data per sector      sectors per track

|                |      |    |
|----------------|------|----|
| SINGLE DENSITY | 128  | 26 |
|                | 256  | 15 |
|                | 512  | 8  |
| DOUBLE DENSITY | 256  | 26 |
|                | 512  | 15 |
|                | 1024 | 8  |

In the header field which precedes the data field of a sector, the track number, the side, the sector number and the sector length are recorded. During read or write commands, this header is read before data transfers take place. Whenever a seek

## Programming Specifications - Disk I/O

command is issued which causes the the read/write head to move to a new track the firmware on the DJ board performs a verify which reads this sector header to make sure the head is positioned correctly and to determine if there is any change in the sector length or the density of the recorded information. If there is an error as to the track number, the firmware automatically issues a seek to track zero command to position the head over a known track.

The disk drive has a sensor that reports when the read/write head is physically positioned at track zero. A series of step out commands must be issued by the 1791 controller until this status line becomes active. This operation will always position the head to the same physical track. The seek to track zero command is often called a recalibrate command and is a standard utility subroutine supplied with the disk firmware.

Transferring a sector of disk data between memory and the disk therefore involves the following steps, each corresponding to a subroutine call to the Disk Jockey firmware (with the exception of error checking):

Specify the track number the read/write head should be positioned over during subsequent data transfers between the disk and memory.

Check for error conditions.

Specify the sector number that will be involved in subsequent data transfers between the disk and memory.

Check for error conditions.

Specify the starting memory address of block of data that is to be transferred to or from the disk.

Check for error condition.

Actually perform the read or write operation.

Check for error conditions.

### ROM SUBROUTINES

TRKSET - The value in the C register of the CPU specifies what track the read/write head will be positioned over when the next disk read or disk write operation is issued. A bounds check is made for a value greater than or equal to zero and less than or equal to 76. If the value in the C register is within these bounds, the contents of the C register is written into the RAM location, TRACK.

## Programming Specification - ROM Subroutines

Otherwise no action is taken, the carry flag is set and the subroutine returns to the calling program.

- SECTOR** - The value in the C register of the CPU specifies what sector will be involved in the next disk read or write operation. A bounds check is made for a value greater than or equal to 1 and less than or equal to 26. If the value the C register is within these bounds, the data in C is transferred to the RAM location SECTOR and a normal return is made. Otherwise no action is taken, the carry flag is set and the subroutine returns to the calling program. Just prior to a disk transfer operation a comparison is made between the value in SECTOR and the maximum number of sectors on the track that transfer is to take place on. If the value in SECTOR exceeds the maximum number of sectors, the transfer operation is aborted and error information is reported.
- SETDMA** - During disk transfer operations blocks of data are moved to and from the disk. These blocks can be 128, 256, 512, or 1024 bytes long. The starting address of a data block that will be involved in the next disk transfer operation is specified by the B-C register pair when the SETDMA subroutine is called. Since the disk registers are memory mapped, the firmware has been designed to try to protect them from being written into or read from during disk transfer operations. Accordingly, a bounds check is performed before the DMA address is recorded in the Disk Jockey RAM. If a 1024 byte data transfer to or from the disk would cause memory references to the I/O registers of the disk controller, the carry flag is set and the routine returns with no action taken. If the value of the B-C pair is such that there could not be any memory references to the last eight locations of the Disk Jockey ROM during a subsequent disk operation, the contents of the B-C pair are written into the memory location of the Disk Jockey RAM specified by the label DMAADR. The carry flag is cleared and the routine ends.
- SELDRV** - The value of the C register determines which of 4 disk drives will be selected for the next disk transfer operation. A bounds check is performed on C. If the value in C is greater than 3, the carry flag is set and the routine returns with no action taken. If the value in C is between zero and three, this data is written in the Disk Jockey RAM at the location specified by the label DISK. The carry flag is cleared and the routine returns to the calling program.
- SETSID** - Double sided floppy disk drives have two read/write heads so that information can be stored and retrieved from both sides of the diskette. The two heads are

## Programming Specification - ROM Subroutines

positioned so that they are both on the same track one directly below the other. They also share common read/write electronics. Therefore only one of these heads can be selected at a time. Bit 0 of the C register is used to select which of the two heads on a double sided drive will be used during the next disk transfer operation. A zero in bit 0 will select the bottom head and a 1 will select the top head. Selecting a side and selecting a disk are independent operations. If side zero is selected then regardless of the disk selected, side zero will always be accessed until SETSID is called. Finally, if the selected disk is single sided, side zero will always be selected regardless of the results of the SETSID routine.

SETDEN - The 1791 Floppy Disk Controller operates in two modes: single density FM (Frequency Modulation) mode or double density MFM (Modified Frequency Modulation) mode. Bit 0 of the C register determines what density the 1791 will be operating in when the next disk transfer operation is initiated. Care must be exercised in the use of this routine. Under certain circumstances, if the density is changed in between disk transfers on the same track, the micro-program that the 1791 controller executes could fall into an error loop that it could not recover from. In such a case the system would have to be reset before further disk operations could be performed. The density mode of the 1791 can safely be changed when a subsequent disk transfer operation will occur on a different track than the last. It should be noted that the firmware of the Disk Jockey has the ability to automatically set the density mode of the 1791. Whenever a new drive is to be selected or whenever the head is not loaded, the Disk Jockey firmware performs a "read header" operation just after positioning the read/write head (if necessary) and just before attempting to perform a disk transfer. This "read header" operation is used to establish the density of the (possibly new) track and to determine the length of the sectors on this track. If the density has not changed from the last "read header" operation or if the calling program has set the density correctly through the use of SETDEN, the process of reading the sector header is slightly faster (by approximately one and a half diskette revolutions) than it would be if the initial assumption concerning the density was wrong.

TKZERO - This subroutine positions the read/write head to the outer-most track of the diskette: track 00. The track zero sensor is used to determine this positioning and no "read header" verify operation is performed. There are several side effects of positioning the head at track zero: (1) a flag is set in the Disk Jockey RAM to force

## Programming Specification - ROM Subroutines

a "read header" density/position verify operation prior to the next disk transfer operation and (2) the mode of the 1791 controller will be forced to single density as long as disk transfer operations occur on track zero. All IBM compatible diskettes have track zero formatted in single density and condition (2) above relieves the system software of the burden of conditionally changing density every time the head is moved to track zero. If the rest of the disk is recorded in double density, the Disk Jockey firmware will automatically switch back to double density when the head is moved away from track zero without the intervention of external software.

**READ -** This subroutine transfers information from the diskette to memory. The first task is to select the proper disk drive. If the new drive is not the same as the current drive, the load head time-out flag is set and the current drive is updated to be the new drive. Next, the "head loaded" flag is tested. If the head is not loaded or if the current drive was not the same as the new drive, the head load time-out flag is set. The firmware then merges the drive select bits with the head select bit and physically selects a drive, loads the head(s), and selects a side (if the drive is double sided). If the head load time-out bit is set, a 40 millisecond delay occurs to allow for the head to settle after loading. Next the "ready" line from the drive is tested. If the drive is not ready, the head is unloaded and the routine returns to the calling program with the carry bit set and an 80H in the A register. If the drive is ready, the head is positioned in accordance with the most recent seek operation. Head motion (including a head load) or a change of disk drive will cause the firmware to verify the track position by doing a "read header" operation. The correct density of the track is also determined during this operation and the density mode is changed if necessary. If the 1791 controller cannot read the header information in either density, the head is moved to track zero, the carry is set, and the read operation is terminated with an 11H in the A register. If the head is correctly positioned, the size of the sectors on the current track is encoded in the Disk Jockey RAM. The firmware uses this information to find the value of the highest addressable sector. This value is compared to the that specified by the most recent set sector operation. If the desired sector has a value too large for the present track, the head is unloaded, the carry flag is set and the routine returns with a 10H in the A register. If the value is acceptable, the data from this sector is transferred to memory starting at the address specified by the most recent set DMA operation. The length of this transfer is

## Programming Specification - ROM Subroutines

determined by the length of the sectors on the current track. The last two bytes of data on the sector are not read into memory. These are the CRC check sum bytes and are used to detect data transfer errors. The 1791 chip processes these bytes and then updates its status register. The last operation that the routine performs is to place the status information in the A register and conditionally set the carry flag. The details of these status bits are illustrated below.

### "DREAD" REGISTER A ERROR BITS

DWRITE - The flow of logic for this routine is exactly the same as described above in the read data operation up to the point where the information transfer is to take place. If all the conditions for a data transfer as described above are satisfied, a write sector command is issued to the 1791 controller and information is transferred from memory to the disk drive starting at the memory address specified by the most recent DMA operation. This data is written on the sector specified by the most recent set sector operation and the head is positioned over the track specified by the most recent seek operation. As the controller writes data on the disk it is continually computing two CRC check sum bytes. After the last byte of data has been written on the diskette, the two check sum bytes are appended to the sector by the controller for later use when the sector is read back into memory. As with the read operation the controller updates its status register after the last CRC byte has been written on the diskette. These status bits are placed in the A register just before control is returned to the calling program. The carry flag is conditionally set from these bits. The details of this status information can be seen below.

Programming Specification - ROM Subroutines

"DWRITE" REGISTER A ERROR BITS

**DBOOT** - Branching to this routine will initiate a bootstrap load operation from the floppy disk. 128 bytes of data will be read (single density mode) into the first half of the 3rd page of the Disk Jockey RAM (normally 340:0000 or E000H). The bootstrap routine terminates with a branch to the first location of this block. Typically sector 1 of track zero will contain another bootstrap program whose job it is to load a Disk Operating System (DOS) such as Disk/ATE or CP/M. If the bootstrap read is not successful, control is passed to the DSKERR utility which is described below. Before sector one is read into memory, various memory locations of the Disk Jockey RAM are initialized. Also DBOOT goes through a several second delay the first time it is called after power-up. In order to effect an orderly start-up sequence, DBOOT does not require that the drive have a diskette in place when it is called. If the drive is not ready when DBOOT is called, it falls into a loop that turns on the LED at the top of the controller and slowly pulses the activity light at the front of the drive. This was done so that DBOOT could be started before a diskette was inserted in the drive. When a diskette has been inserted, the door should be closed just AFTER the activity light has been pulsed.

**DMAST** - This subroutine loads the B-C register pair with the current value of the DMA address recorded in the Disk Jockey RAM.

**STATUS** - This subroutine loads the B register with the sector number involved in the last disk transfer operation. It loads the C register with the track number the head is currently positioned over. Finally, it loads the A register with a bit pattern indicating the drive involved in the last disk transfer operation, the length of the sectors on the current track, the side specified by the last SETSID call, and whether or not data on the current track is written in single or double density format. The details of how this information is encoded in the A register is presented below.

Programming Specification - ROM Subroutines

A REGISTER BIT PATTERN

| DRIVE MSB | DRIVE LSB | DRIVE NO. |
|-----------|-----------|-----------|
| 0         | 0         | DRIVE A   |
| 0         | 1         | DRIVE B   |
| 1         | 0         | DRIVE C   |
| 1         | 1         | DRIVE D   |

| SIDE BIT | SIDE SELECTED |
|----------|---------------|
| 0        | SIDE 0        |
| 1        | SIDE 1        |

| SECTOR LENGTH MSB | SECTOR LENGTH LSB | SECTOR LENGTH | DENSITY |
|-------------------|-------------------|---------------|---------|
| 0                 | 0                 | 128           | SINGLE  |
| 0                 | 1                 | 256           | DOUBLE  |
| 1                 | 0                 | 512           | DOUBLE  |
| 1                 | 1                 | 1024          | DOUBLE  |

DSKERR - Calling this routine will put the CPU into a loop which will cause the LED (Light Emitting Diode) at the top left portion of the controller board to flash on and off at intervals of about a second. This routine takes no parameters and will not return-- its primary usefulness is to indicate when a hard error has occurred during the bootstrap load operation.

## Programming Specification - ROM Subroutines

### DISKETTE INITIALIZATION

Before a new diskette can be successfully used, it must be initialized. Most diskettes are sold pre-initialized. However, it is sometimes necessary to reinitialize a diskette. The process of initializing a diskette involves writing the header field of every sector of every track onto the diskette. None of the subroutines described above can be used to write these header fields. This is a safety measure to ensure that an erroneous branch to the firmware PROM cannot re-initialize a diskette, destroying all the data recorded on it. The initialization function for diskettes is typically provided by a command included in the Disk Operating System. Disk/ATE diskettes furnished by Morrow's/Thinker Toys contain commands FMT128, FMT256, FMT512 and FMT1024 to allow the user to format diskettes in any of the four IBM compatible formats. CP/M diskettes from Thinker Toys contain a command called FORMAT which allows the CP/M user to format diskettes in single or dual density.

## UTILIZING DISK JOCKEY FIRMWARE

Data transfers to and from the disk must be preceded by calls to certain Disk Jockey routines. The function of these routines is to set up parameters that will be used during the transfer. The following procedure is suggested:

- 1) Select the drive to be involved in the transfer. This is accomplished by calling the routine "SELDRV" with the proper drive number in register C. The drive need not be selected before every transfer. A drive once selected will remain selected until another drive is specified. For 2-headed drives, the side of a drive should be specified by calling the SETSID routine with the desired side number in the C register.
- 2) If the drive has not been accessed before, the read/write head of the drive is in an unknown position. To initialize the drive a call should be made to "TKZERO" in order to bring the head to track zero.
- 3) Set the DMA address. This involves calling the routine "SETDMA" with the correct value in the B-C register pair. It is not necessary to set the DMA address before every data transfer. If data is always being read into the same area of memory, then only one "SETDMA" call need be made.
- 4) Set the read/write head over the desired track. This involves a call to "TRKSET" with the desired track number in register C. It is only necessary to call the "TRKSET" routine when changing tracks. If the data transfer involves the same track as the previous transfer then no call to "TRKSET" should be performed.
- 5) Set the desired sector number. The sector can be set by calling "SETSEC" with the correct sector number in register C. If the sector has not changed since the previous "SETSEC" call, as with a read-modify-write sequence, then this routine may be skipped.
- 6) Read or write the desired sector. The controller can now be commanded to read or write to the disk by calling "DREAD" or "DWRITE".

The order in which these operations occur is not important with the exception that the "DREAD" or "DWRITE" routine must be called last.

## Utilizing Disk Jockey Firmware

### Data Transfer Examples

#### READ:

Suppose sectors 5, 6, 7 and 8 of track 12, drive 1 are to be read into memory starting at location 7:0000 (700H). The following program will do this:

## DISK SYSTEM SOFTWARE

An assembled Disk Jockey 2D is part of a DISCUS 2 system and is also accompanied by a copy of Disk/ATE (tm). Both Disk/ATE and the Disk Jockey 2D CP/M are tailored to the I/O of the Disk Jockey 2D controller. Both expect that a serial TTY/RS-232 terminal is connected to J2 (serial port) of the Disk Jockey. Both are supplied on a write protected diskette (notch open) which should be kept that way. DO NOT COVER THE NOTCH ON THE DISKETTE. Finally, both systems are designed to self load when the disk is placed in drive A and a branch is made to 340:000Q (E000H). For CP/M users, the CP/M diskette is accompanied by a series of manuals describing how to back-up a CP/M diskette. The only precaution is that when drive B is to be used for the back-up, it must be "logged in" (e.g., DIR B:) before the back-up process begins.

### Backing Up Disk/ATE

To make a back-up copy of Disk/ATE, load Disk/ATE and have a blank diskette which is not write protected (the notch should be covered). Follow the steps outlined below:

#### If You Have a Dual Drive System:

- 1) Perform steps 6 and 7 below, inserting the blank disk in drive B.
- 2) Type: TD A B  
TD is the transfer disk command with the source drive on the left and the destination drive on the right. This command will copy all the files on drive A to drive B.

#### If You Have a Single Drive System:

- 1) Type: B16  
This command forces ATE to express numbers and addresses in hexadecimal radix.
- 2) Type: L IO2DTBL <T>  
This command loads the I/O driver symbol table from the disk. After the symbol table is loaded, ATE will be able to search the table for variable values. Some variables will be necessary to accomplish the back-up.
- 3) Type: ? SYSIO.IOEND  
This is the standard way of interrogating ATE to find the value of variables. SYSIO is the beginning of the I/O driver, and IOEND is the end of the driver. Make a note of these two values because we will need them later.

## Disk System Software

- 4) Type: L ATETBL <T>  
This loads a different symbol table from the disk and overwrites the previously known symbols.
- 5) Type: ? BEGIN.END  
The two parameters typed back represent the extent of ATE except for disk buffers. Make a note of these two values also.
- 6) Type:  
GO FMT128 to format single density  
GO FMT256 to format double density with 256 byte sectors  
GO FMT512 to format double density / 512 byte sectors  
GO FMT1024 to format double density / 1024 byte sectors  
This loads and executes the desired format program. The purpose of this routine is to write the IBM standard sector header and data marks out on the disk, and to put a bootstrap on track zero.
- 7) The selected format program prompts the user through the necessary steps to format a diskette and automatically returns to Disk/ATE when the operation is complete.
- 8) IO2D and ATE must now be saved on the new diskette. IO2D must be the first file on the disk, and ATE must be the second.
- 9) Using the values for SYSIO and IOEND obtained from step 3 above, Type: S IO2D (SYSIO value here)H.(IOEND value here)H The "H" suffix is necessary to force ATE to interpret the preceding number as a hexadecimal number.
- 10) Using the values for BEGIN and END obtained in step 5, Type: S ATE (BEGIN value here)H.(END value here)H
- 11) Disk/ATE has now been copied on the fresh diskette. Files may now be transferred from the original diskette as required.

### Backing up other files

Once IO and ATE have been backed up on a diskette, some of the other files on the original diskette from Thinker Toys may need to be moved onto the backup media. There are two types of files presently supported by Disk/ATE: Source and binary. The source files always load into the source area of Disk/ATE and may also be saved on another diskette from the same source area. The Disk/ATE user's manual describes this procedure in detail. When a binary file is first saved on a diskette by Disk/ATE, the starting address is recorded in the directory entry along with the length. The STAT command will display the starting address of a binary file along with its length. The length is given in

## Disk System Software

increments of 1024 bytes (k). Hence there are 2560 bytes in a file that is 2.5k long. When the file is loaded into memory, unless otherwise specified (see the Disk/ATE user's manual) it will be loaded starting at the address displayed by the STAT command and ending at the address which is the sum of the starting address and the file length. This file can be saved on another diskette (which has been previously formatted) by simply placing the diskette in the drive and typing a S(ave) command followed by the proper beginning and ending address. As an example, the binary file FMT1024 is 3.0k long and has a starting address of 65:0000 (3500H). To save this file on a back-up diskette, the following steps need to be performed:

- 1) Put the disk that has FMT1024 on it in the drive.
- 2) Type: L FMT1024
- 3) Place the back-up diskette in the drive.
- 4) Type: S FMT1024 65:0000..100:3770

This completes the operation. If the write protect notch of the diskette is not covered on the back-up diskette, Disk/ATE will report a disk error and the operation will have to be done over with the notch covered.

## The Bootstrap loader

Both Disk/ATE and copies of CP/M which are purchased through Thinker Toys are supplied on diskettes which load into the system through the use of the bootstrap loader DBOOT. To use DBOOT the system should be turned on and the CPU's program counter should be initialized to 340:0000 (E000H) either from the front panel of the computer or through jump-start logic either on the controller or on some other board in the system. A 2-3 second delay occurs the first time DBOOT is called after power-up so that the system has time to stabilize before the disk is accessed. Power should be applied to the drive(s) that are connected to the Disk Jockey controller at approximately the same time it is supplied to the CPU. However the system should be given time to stabilize before a diskette is inserted a drive. DBOOT always loads from drive A. If a diskette is not in place when DBOOT is started, the activity light at the front of drive A is slowly pulsed to indicate that the bootstrap loader is waiting for a diskette to be inserted in the drive and the door to be closed. The proper time to close the door is just AFTER the activity light has flashed. Shortly after the door is closed the drive signals the controller that it is ready and a loader program on sector one of track zero is read into the Disk Jockey RAM. When DBOOT is finished, it transfers control to this secondary loader.

I/O CONNECTORS J1 AND J2

Illustrated below are the details of the pin connections of J1 and J2. In both illustrations, the top of the circuit board is to the right of the drawing. The end pins of both connectors are numbered on the silk screen legend of the PC board. Note that all disk interface signals are active low.

|              |   | J2  |  |                 |   | J1  |              |
|--------------|---|-----|--|-----------------|---|-----|--------------|
|              |   | --- |  |                 |   | --- |              |
|              |   |     |  |                 |   | 50  | * *   49 GND |

## PATCHES FOR CP/M\*

### General

This section is included for those users of the Disk Jockey 2D who have purchased a copy of CP/M Vers. 1.4 from a source OTHER than Thinker Toys. Copies of CP/M sold through Thinker Toys have the necessary I/O routines to interface CP/M to the Disk Jockey controller and to the DJ2D's serial I/O facility. These patches will help create a SINGLE DENSITY CP/M diskette-- NOT a double density one. Though this may seem of marginal interest at first glance, we would point out that this section, combined with the software listings provided in the back of this manual, constitutes an excellent example of interfacing the Discus 2D to a significant disk operating system.

At the end of this section are two listings which are designed to allow the Disk Jockey to be interfaced with the Digital Research CP/M operating system. This can be done with a minimum of effort.

The first listing is the so called "cold start loader" which is used to bring CP/M in from the disk. It also has code which will allow the user easily to write a modified version of CP/M out on the disk. There is even a small routine which writes the "cold start loader" itself on sector 1 of track 0.

The second listing is CBIOS software (Custom Basic Input-Output System) which is the interface between CP/M and the Disk Jockey controller. The general idea is to key in the cold start loader, use the loader to bring CP/M in from a diskette, enter the CBIOS code and, finally, use the cold start loader to save everything out on a clean diskette.

### The "Cold Start Loader"

There are three parts to the cold start loader. LOAD is at address 347:000Q (0E700H) and is designed to read CP/M into memory from location 51:000Q (2900H) to 77:377Q (3FFFH). After loading CP/M, the LOAD routine branches to location 76:000Q (3E00H) which is a routine that initializes several memory locations, prints a sign-on message, and then branches to CP/M proper.

SAVE is at location 347:111Q (0E749H) and is the reverse of LOAD. SAVE writes out on the disk starting at track 0 sector 2 all memory locations between 51:000Q (2900H) and 77:377Q (3FFFH). After performing this operation, SAVE comes to a dynamic halt at STALL 347:133Q (0E75BH).

\*CP/M is a trademark of Digital Research

## Patches for CP/M

INTLZ is a short routine which writes locations 347:0000 (0E700H) through 347:1770 (0E77FH) on sector 1 of track 0. Thus, once the cold start loader is keyed into memory, it can save itself at the right location on the disk.

## CBIOS

The standard version of CP/M is designed to run with the Intel MDS development system and floppy disk interface. Most of the CP/M system software is completely independent of the particular 8080 hardware environment in which it happens to be running. However, there is a certain part which must be tailored to the hardware of the host system. This hardware dependent software is completely contained on pages 76 and 77 of CP/M memory (assuming the standard 16K version). CP/M can be made to run on different hardware by changing the software on pages 76 (3E00H) and 77 (3F00H). The CBIOS software which is supplied with the Disk Jockey is designed to let CP/M run when an eight inch full sized floppy disk is attached to the Disk Jockey controller that is plugged into an S-100 main frame.

## Patching CP/M

Before actually performing any of the steps below, the Disk Jockey should be plugged into an S-100 bus mainframe, and an 8" disk drive should be connected to the controller. Be sure to observe correct cable orientation. You should have on hand two diskettes: one with CP/M and a blank one that has been formatted. A copy of CP/M which will run on the Disk Jockey will be constructed on the blank disk before any changes are attempted on the original CP/M disk. As a precaution, the diskette with the CP/M binary should have a write protect notch and this notch should NEVER be covered during the following steps.

### Step I:

Plug in the controller. Connect the disk to the controller and turn on the the CPU and the disk drive. Do NOT put a diskette in the drive at this time.

## Patches for CP/M

### Step II:

Be sure the drive is on and the door is OPEN. Initialize the CPU's program counter to 340:0000 and start the machine. After a several second delay, the LED at the top of the controller should turn on and the activity light (if one is present) on the front of the drive should flash briefly every several seconds. Various memory locations in the Disk Jockey RAM are now initialized and the firmware is ready to perform disk transfer operations. Stop the CPU.

### Step III:

Enter the "cold start loader" into memory starting at location 347:0000 (0E700H). The instructions will extend from 347:0000 (E700H) to 347:1770 (0E77FH), filling most of the first half of the last page of RAM on the controller.

### Step IV:

Set the program counter of the CPU to location 347:1420 (0E762H), but do NOT start the CPU yet.

### Step V:

Insert the BLANK diskette into the drive and close the door. Be sure that the diskette is NOT write protected. (An 8" write protected diskette has a notch near the corner of the diskette diagonally oppoiste the labled corner.) If this notch is missing or covered, the diskette is not write protected. Be sure the diskette is inserted right side up. On a Disk Jockey system, the label will be on the top. The diskette is inserted in the drive with the label held bewteen the thumb and forefinger.

### Step VI:

Start the computer. The drive activity light (if one is present) will come on, the head will load and step out to track 0 unless it is there already. After sixteen revolutions of the diskette, the head will unload and the activity light will go off.

### Step VII:

Stop the CPU. It should be in the tight loop JMP DONE -- 303 171 347 octal (C3 79 E7 hex). The cold start loader has been written on sector 1 of track 0.

## Patches for CP/M

### Step VIII:

Remove the diskette from the drive.

### Step IX:

Change location 347:001Q (0E701H) from 000Q (00H) to 133Q (5BH) and change location 347:002 (0E702H) from 76Q (3EH) to 347Q (0E7H).

### Step X:

Initialize the program counter of the CPU to 347:000Q (E700H) but do NOT start the machine.

### Step XI:

Insert the CP/M diskette and be sure that the write protect notch is not covered. Close the door securely

### Step XII:

Start the CPU. The head will load and after a second or two the head will step to track 1. Wait for the head to unload and the activity light to go off. CP/M has been loaded into memory between 51:000Q (2900H) and 77:377Q (3EFFH).

### Step XIII:

Enter the CBIOS code starting at 76:000Q (3E00H). Be sure to check that the code has been entered correctly.

### Step XIV:

Initialize the program counter of the CPU to 347:111Q (E749H) but do NOT start the CPU.

### Step XV:

Take the diskette which has the cold start loader on track 0 sector 1 and place it in the drive. Be sure that this diskette is still write enabled (the notch should be covered).

### Step XVI:

Start the CPU. The head should load, return to track 0 and write the better part of tracks 0 and 1 before it unloads. After the head unloads, remove the diskette and remove the write enable tab from the diskette. Stop the CPU. The CPU should be executing the JMP STALL instruction -- 303 133 347 octal (C3 5B E7 hex).

## Patches for CP/M

### Step XVII:

Connect a terminal to the serial port of the Disk Jockey and adjust the baud rate, parity, stop bits, and word length of the terminal and controller so that they match.

### Step XVIII:

Inspect the diskette which was removed in step XVI. Be sure that the write protect notch is NOT covered. Insert the diskette in the drive once again. Initialize the CPU's program counter to 340:000Q (E000H) and start the machine. After a few seconds the terminal should print:

```
16K CP/M VERS/1.4
```

After a few more seconds the prompt should appear:

```
A>
```

A Disk Jockey version of CP/M is now up and running. After this new version of CP/M has been tested (as documented in the CP/M manual), Steps I through XVII can be used to alter the original CP/M diskette if desired.

## HARDWARE LEVEL REGISTERS

Users desiring a greater level of control over the floppy disk or serial interface may wish to refer directly to the I/O device registers on the DJ from their 8080 or Z80 program. There are thirteen one-byte registers-- five of them read only, five write only and three read/write. The registers have eight memory addresses on the S-100 bus with a different register being selected during a read operation and a write operation when the addressed register is read only or write only.

The 1791 controller comprises one of the read only registers (status register), one write only register (command register), and all three of the read-write registers (track, sector, and data registers). The uses of these registers will be touched on only briefly here as there is included in the documentation a detailed data sheet describing the way in which the 1791 controller functions.

The 1602 UART comprises two of the read only registers (input data and status registers) and one of the write only registers (output data). As with the 1791, we do not describe these registers in great detail since a data sheet for the 1602 is also included in the documentation.

The 1791 controller has a negative logic data bus. For this reason the internal bidirectional data bus of the DJ board is also negative logic. However, the bus of the 1602 UART is positive logic. This means that when references are made to the UART registers, the signal levels are opposite to what one would normally expect. In practice then, one should always invert data just before it is written into the UART output register; likewise, data read from the UART should be inverted before it is interpreted.

### READABLE REGISTERS

Register 0 - The inverted UART data output register  
Location 343:370 (E3F8 hex) standard Disk Jockey:

Data is stored in this register by the UART after it has been assembled from the serial data input stream. When a new character is assembled and transferred to this register, the UART sets the DR (Data Ready) flag. When this register is read by the CPU, the DR flag is reset by the UART hardware.

Register 1 - The inverted UART status register  
Location 343:371 (E3F9 hex) standard Disk Jockey

Only the low order five bits of this register have any significance. The meaning of these bits is presented below. The 1602 data sheet should be referred to for a more detailed discussion of these bits. We shall list these signals using

## Hardware level registers

their positive logic mnemonics with the understanding that the actual signals read will be the negation of these mnemonics.

### INVERTED UART STATUS BITS

FE = Framing Error  
TBRE = Transmitter Buffer Register Empty  
DR = Data Ready  
OE = Overrun Error  
PE = Parity Error

REGISTER 2 - Disk Jockey status register  
Location 343:372 (E3FA hex) standard Disk Jockey

This register contains bits that identify the current status of the Disk Jockey and the currently selected drive. Only the six low order bits have any significance in this register. The meanings of these bits are presented below:

### DISK JOCKEY STATUS REGISTER

Bits marked with an asterisk reflect the current state of the status lines from the currently selected floppy disk drive. For a detailed specification of these signals see the documentation that accompanys the floppy disk drive. If no drive is currently selected or if the head is not loaded these bits are all high.

NREADY - This bit is a 0 when the currently selected drive is powered up with a diskette in place and the door closed.

NINDEX - This line reflects the status of the INDEX line from the floppy disk drive. It goes to a 0 once per revolution of the diskette.

N2SIDED- This line is a 0 when a double sided drive is connected to the controller AND there is a double sided diskette in place in the drive with the door closed.

## Hardware level registers

HEAD - When this line is a 1 the head of the currently selected floppy disk drive is loaded.

DATARQ - When this line is a 1 the data request line from the 1791 controller is high and the controller is requesting that its data register be read from or written to. When the data register is referenced, this line will change to a 0.

INTRQ - The 1791 controller sets this line to a one whenever it has completed a command and is no longer busy. This line is reset by a reference to the command register or the status register of the 1791 controller.

Register 3 - Not currently used  
Location 343:373 (E3FB hex) standard Disk Jockey

Register 4 - 1791 controller status register  
Location 343:374 (E3FC hex) standard Disk Jockey

This is the status register of the 1791 controller. The meaning of the bit patterns of this register varies depending upon the command that the controller is executing or has executed. See the 1791 data document for a detailed discussion of this register.

## WRITE ONLY REGISTERS

Register 0 - The inverted UART data input register  
location 343:370 (E3F8 hex) standard Disk Jockey

Inverted data is stored in this register by the CPU for serial output by the UART. The UART transfers the data from this register to an internal parallel load serial output register where the start bit optional parity bit and the stop bits are appended to the data. Whenever the UART empties register 0, the TBRE status bit is raised to inform the CPU that it is possible to output more data to the UART.

Register 1 - Disk Jockey drive control register  
location 343:371 (E3F9 hex) standard Disk Jockey

This is a six bit register that is used by the Disk Jockey to select one of four drives, select side one or two for double sided drives, and to turn on and off the error flag LED built into the board near the serial connector J2. Only the low order six bits of this register have any significance. The meanings of these bits are presented below.

## Hardware level registers

### DRIVE CONTROL REGISTER

- LED OFF - When a zero is stored in this bit the LED at the top of the board near J2 is turned on. A one stored in this bit turns off the LED.
- SIDE 0 - When a double-sided drive is connected to the Disk Jockey a one stored in this bit selects head 0 while a zero selects head 1. When a single-sided drive is connected to the Disk Jockey, this bit has no effect on the drive.
- NDRIVED - When this bit is a zero and the head is loaded the fourth or last drive is selected. A one written in this bit will deselect the last drive.
- NDRIVEC - This is the drive select bit for the third drive connected to the Disk Jockey. A zero selects the third drive when the head is loaded while a one deselects the third drive.
- NDRIVEB - The drive select bit for the second drive connected to the Disk Jockey. When the head is loaded, a zero in this bit will select the second drive while a one will deselect it.
- NDRIVEA - The drive select bit for the first drive connected to the Disk Jockey. A zero in this bit will select the first drive when the head is loaded and a one will deselect it.

Only one of the four low order bits of this register should ever be a zero. If more than one of these bits are zero, loading the head will select more than one drive and cause data errors during reads and possible head position errors on seeks.

Register 2 - The Disk Jockey function register  
Location 343:372 (E3FA hex) standard Disk Jockey

Only the low order six bits of this register have any significance. Two bits load and unload the read/write head of the drive, one determines the density mode that the 1791 controller operates at, another turns on and off the VCO of the phase-lock loop, and yet another controls the master reset of the 1791 controller. The final bit controls the way that the CPU will access the data register of the 1791. During power-up, this register is initialized so that it is as if ones had been written

## Hardware level registers

in all six bits. The specific function of the various bits is detailed below.

### DISK JOCKEY FUNCTION REGISTER

- VCOFF - This bit controls the voltage controlled oscillator (VCO). A one written in this bit will turn the VCO off while a zero will turn the VCO on. The VCO must be on to read data from the disk.
- CLRFDC - A one written in this bit will reset the 1791 controller. The chip will remain in the reset state until this bit is changed to a zero. When the reset signal is removed the 1791 executes a restore (seek to track zero).
- AENBL - During data transfers, when the CPU references the 1791's data register the PREADY line (S-100 bus line 72) is brought low which puts the processor in a wait state. The CPU remains in this state until the 1791 raises its DATA REQUEST line. This mode of operation dispenses with the usual status test during data transfers and makes it possible for the Disk Jockey to run at double density speeds without having to use a DMA channel. However there are times when the CPU needs access to this register when the DATA REQUEST is low (before a seek command is issued for example). When the AENBL bit is a one the stall logic that usually governs accesses to the 1791's data register is disabled. This allows the CPU to have access to this register as if it were a normal memory location. However, before the Disk Jockey can correctly transfer data to or from the floppy disk drive, this bit must be a zero so that the CPU can synchronize its data transfers to the 1791 controller.
- SINGLE - When this bit is a one, the DJ board will read and write data to and from the disk in single density. When this bit is a zero, reads and writes are performed in double density.

## Hardware level registers

HD0, HD1 - These two bits control the loading of the read/write head. Their functional character is detailed in the table below.

| HD1 | HD0 | Read/write head function |
|-----|-----|--------------------------|
| 0   | 0   | not allowed              |
| 0   | 1   | head is loaded           |
| 1   | 0   | head is unloaded         |
| 1   | 1   | 1791 may unload head     |

Register 3 - Not currently used  
Location 343:373 (E3FB hex) standard Disk Jockey

Register 4 - 1791 controller command register  
Location 343:374 (E3FC hex) standard Disk Jockey

This is the command register of the 1791 controller. There are four different classes of commands and within each class there are a number of separate commands that the controller can execute. See the 1791 data document for a detailed discussion of this register and its use.

### READ-WRITE REGISTERS

Register 5 - 1791 track register  
Location 343:375 (E3FD hex) standard Disk Jockey

The 1791 controller uses this register as a reference to where the read/write head of the disk drive is positioned. Extreme care should be exercised when writing in this register. If care is not exercised, seek errors may likely occur. See the 1791 data document for a more detailed discussion.

Register 6 - 1791 sector register  
Location 343:376 (E3FE hex) standard Disk Jockey

This is the sector register of the 1791 controller. Only one of the commands will cause the 1791 to write in this register. Generally the 1791 uses this register to determine which sector is to be read or written. See the 1791 data document for a more detailed discussion.

Register 7 - 1791 data register  
Location 343:377 (E3FF hex) standard Disk Jockey

This is the data register of the 1791 controller. Data is written into this register when the controller is writing to the disk. Data is read from this register when the controller is

## Hardware level registers

reading from the disk. The desired track number is also written in this register when seek commands are issued to the controller. As before the 1791 data document should be referred to for a more complete discussion

### FINAL NOTE

The Disk Jockey firmware contains numerous examples illustrating the use of the hardware registers listed above. A comprehensive study of the two Western Digital data documents along with a careful examination of the Disk Jockey firmware will equip the interested user with enough knowledge to control the disk drive at the hardware level.

DJ2D REVISION 4 PARTS LIST

|     |    |   |
|-----|----|---|
| [ ] | 1  | 5" x 10" printed circuit board  |
| [ ] | 1  | 240 Ohm 1/4 watt 5% resistor red-yellow-brown   |
| [ ] | 3  | 330 Ohm 1/4 watt 5% resistors orange-orange-brown   |
| [ ] | 2  | 470 Ohm 1/4 watt 5% resistors yellow-purple-brown   |
| [ ] | 2  | 750 Ohm 1/2 watt 5% resistors purple-green-brown  |
| [ ] | 12 | 1k Ohm 1/4 watt 5% resistors brown-black-red  |
| [ ] | 1  | 1.5k Ohm 1/4 watt 5% resistor brown-green-red   |
| [ ] | 3  | 3.3k Ohm 1/4 watt 5% resistors orange-orange-red  |
| [ ] | 3  | 4.7k Ohm 1/4 watt 5% resistors yellow-purple-red  |
| [ ] | 2  | 5.36k Ohm 1/8 watt 1% resistors - These two parts replace the 6.19k 1% resistors which appear on the parts legend of the circuit board.                 |
| [ ] | 2  | 10k Ohm 1/4 watt 5% resistors brown-black-orange  |
| [ ] | 1  | 11.0k Ohm 1/8 watt 1% resistor - This part replaces 13.0k 1% resistor which appears on the parts legend of the circuit board.                           |
| [ ] | 2  | 27k Ohm 1/4 watt 5% resistors red-purple-orange   |
| [ ] | 1  | 47k Ohm 1/4 watt 5% resistors yellow-purple-orange  |
| [ ] | 4  | 1 Megohm 1/4 watt 5% resistors brown-black-green  |
| [ ] | 1  | 180 Ohm 1/8 watt 5% 9 resistor SIP array  |
| [ ] | 2  | 3.3k Ohm 1/8 watt 5% 9 resistor SIP array   |
| [ ] | 3  | 33 picofarad 5% silver mica capacitors - Two of these parts replace the 100 picofarad capacitors which appear on the parts legend of the circuit board. |
| [ ] | 2  | 47 picofarad 2% or 1% silver mica capacitors  |
| [ ] | 1  | 112 picofarad 2% or 1% silver mica capacitor  |
| [ ] | 1  | 470 picofarad 5% silver mica capacitor  |
| [ ] | 1  | .001 microfarad disk capacitor  |
| [ ] | 1  | .01 microfarad mylar capacitor  |

DJ2D Revision 4 Parts List

|     |    |  |        |
|-----|----|--|--------|
| [ ] | 1  | 1.5 microfarad dipped tantalum capacitor   |        |

## CABLE CONNECTIONS

Drives on Discus systems are connected in daisy chain fashion to the controller board, as illustrated below.

As can be seen from the above figure, Drive A is located at one end of the cable and is the only terminated drive on the cable. The location of any additional drives on the cable is not important as long as they are not at the end of the cable. Again, extra drives are not terminated.

Aside from termination, the only physical difference between an "A" and a "B" drive, or between any two differently addressed drives, is the jumper strapping on the PC board of the drives. Strapping a drive for termination and drive selection is documented in the Shugart OEM manual.

Four different daisy chain cables are available for one, two, three or four drive systems. A daisy chain cable is simply a parallel cable. Not all available connectors on a multiple drive cable need be filled for the system to function. Also, a dual system with drives addressed, say, as "A" and "C" would work fine as long as the operator remembered to refer to the second drive as "C" rather than "B". In other words, the absence of a "B" drive in no way "locks out" the "C" and "D" drives.

The following rule applies to all cable configurations supplied by Thinker Toys:

The 50 pin flat ribbon cable provided with the Discus system should be connected to the Disk Jockey controller board so that the cable extends out over the solder side of the PC board-- not the component side.

Whichever end of the 50 pin flat ribbon cable is chosen to plug into the controller board, that side of the cable which is on the LEFT (closer to the heat sink) as it connects to the controller should be UP as it connects to each and every drive on the system. Thus, J1 pin 50 on the DJ controller board should come in to each disk drive via the top part of the male 50 pin connector attached to the cabinet of each drive. If the LED on the front of the drive comes on upon power up, the cable is on backwards and should be reversed. The LED on the front of the drive should light up only when a command has been issued to load the head.

Any visual "key" such as an arrow or triangle on a connector should be used solely as an aid in implementing the connection scheme described above.

## SERIAL I/O SWITCH SETTINGS

### BAUD RATE SELECTION

Paddles 1 to 4 of Switch 2 in the lower right corner of the DJ control the baud rate for the 1602 UART. Sixteen separate baud rates, ranging from 50 to 19,200, are available. The following table lists all possible switch settings for baud rate selection.

### BAUD RATE SWITCH SETTINGS

| SW2-1 | SW2-2 | SW2-3 | SW2-4 | BAUD RATE |
|-------|-------|-------|-------|-----------|
| on    | on    | on    | on    | 50        |
| on    | on    | on    | off   | 75        |
| on    | on    | off   | on    | 110       |
| on    | on    | off   | off   | 134.5     |
| on    | off   | on    | on    | 150       |
| on    | off   | on    | off   | 300       |
| on    | off   | off   | on    | 600       |
| on    | off   | off   | off   | 1200      |
| off   | on    | on    | on    | 1800      |
| off   | on    | on    | off   | 2000      |
| off   | on    | off   | on    | 2400      |
| off   | on    | off   | off   | 3600      |
| off   | off   | on    | on    | 4800      |
| off   | off   | on    | off   | 7200      |
| off   | off   | off   | on    | 9600      |
| off   | off   | off   | off   | 19200     |

### WORD LENGTH

Paddle 7 of Switch 2 controls data word length selection for the 1602 UART. Placing paddle 7 in the "on" position sets the word length to 7 bits, while "off" fixes the word length to 8 bits. The table below gives the word length selection settings for the DJ.

### WORD LENGTH SELECTION

| SW2-7 | WORD LENGTH |
|-------|-------------|
| "on"  | 7 BITS      |
| "off" | 8 BITS      |

## Serial I/O Switch Settings

### STOP BIT COUNT

SW2-5 controls the number of stop bits, either one or two, which the UART sends after each data word. The "off" position will set the device to two stop bits, and the "on" position to one.

Most devices are extremely tolerant concerning stop bit setting. As a general rule, if a device fails to communicate with the Disk Jockey, it is not because the stop bit setting is incorrect.

#### STOP BIT COUNT SELECTION

| SW2-5 | STOP BIT COUNT |
|-------|----------------|
| "on"  | 1 STOP BIT     |
| "off" | 2 STOP BITS    |

### PARITY

If paddle 6 of switch 2 is in the "off" position, the UART will not generate any parity bits at the end of the serial data word. If the paddle is in the "on" position, refer to the table below for the proper parity setting via paddle 8.

#### PARITY SWITCH SETTING

| SW2-8 | PARITY      |
|-------|-------------|
| "on"  | ODD PARITY  |
| "off" | EVEN PARITY |

POWER-ON JUMP TABLE WITH 74LS240'S AT 5D AND 6D

(REV 3 BOARDS SHOULD USE 244'S ONLY)

SET PADDLE 6 OF SW1 TO "off" FOR 74LS240'S

SET PADDLE 7 OF SW1 TO "on" TO ENABLE POWER-ON JUMP

(SW1 is the switch to the LEFT)

| JUMP ADDRESS |      | SWITCH SETTING |                |                |                |                |
|--------------|------|----------------|----------------|----------------|----------------|----------------|
| Octal        | Hex  | SW1-1<br>(A15) | SW1-2<br>(A14) | SW1-3<br>(A13) | SW1-4<br>(A12) | SW1-5<br>(A11) |
| 000:000      | 0000 | off            | off            | off            | off            | off            |
| 010:000      | 0800 | off            | off            | off            | off            | on             |
| 020:000      | 1000 | off            | off            | off            | on             | off            |
| 030:000      | 1800 | off            | off            | off            | on             | on             |
| 040:000      | 2000 | off            | off            | on             | off            | off            |
| 050:000      | 2800 | off            | off            | on             | off            | on             |
| 060:000      | 3000 | off            | off            | on             | on             | off            |
| 070:000      | 3800 | off            | off            | on             | on             | on             |

## BOOT LED

Near the upper left corner of the DJ2D board, just to the right of terminal connector J2, is the boot LED. This LED will flash on and off if the DBOOT routine reports an error. Since the boot routine is not affected by terminal I/O, this LED can help in determining whether a no-go attempt at bringing up an operating system is due to faulty I/O hardware and/or drivers or due to some other cause-- memory, media, controller, CPU etc.

## PHANTOM ENABLE

The DJ2D will respond to the PHANTOM line-- S-100 pin 67-- if paddle 8 of SW4 is placed in the 'on' position. This paddle is the lowest paddle of the LEFT switch, at location 4D. The DJ2D will become de-selected when the PHANTOM line goes active if this paddle is 'on'. If this paddle is placed in the 'off' position, the DJ2D will ignore the PHANTOM line. In order for the Power-on Jump feature of the DJ2D to work on a SOL computer, the PHANTOM Enable Switch must be 'on'.

## POWER STABILIZATION

When booting a disk for the first time after powering up, the head on Drive A will not load (as evidenced by the LED on the drive door release) for a second or two. After this initial boot, all subsequent boots should load the head immediately until power is turned off and on (erasing memory). During a boot, the firmware on the DJ2D searches its internal RAM for a bit pattern to indicate that at least one boot has taken place since power up. If no such bit pattern is present, a short delay will be inserted to allow all components in the system to stabilize.

## BOOTING WITHOUT A DISKETTE

If no diskette has been placed in Drive A and a boot is attempted (as is often the case during a power-on-jump when a system is first powered up), the LED on Drive A will flash on briefly about once every second. It is possible to execute a boot in this mode. Insert the system diskette into Drive A. Do not lower the drive door, but push the diskette into the drive far enough so that it locks into place (the higher the drive door, the easier for the diskette to lock into place). Wait for the red LED on the diskette release button to flash on and off and, when it goes off, close the drive door. The diskette will boot the next time the LED goes on.

## ASSEMBLY INSTRUCTIONS

WARNING! IMPROPER ASSEMBLY OF THIS KIT WILL VOID THE WARRANTY. READ THESE INSTRUCTIONS CAREFULLY BEFORE ATTEMPTING TO CONSTRUCT THIS KIT

### INVENTORY

Make sure that all parts listed in the Parts List have been included. Notify Thinker Toys immediately if any are missing. Also, quickly return all extra parts.

### USE BENDING BOARD

With the exception of the axial tantalum capacitors and the 1/2 watt 750 Ohm resistors, all the resistor and diode leads should be bent to .5 inches. The leads of the 750 Ohm resistors should have a spacing of .6 inches. The axial lead tantalum capacitors should be bent to .7 inches. Use of a bending block will give your finished kit a more professional look.

### USE SOCKETS

Sockets are provided for every IC on the Disk Jockey.

NO REPAIR WORK WILL BE ATTEMPTED ON ANY RETURNED BOARD WITH ANY IC SOLDERED DIRECTLY TO THE CARD

### ORIENTATION

When this manual refers to the bottom of the circuit board it means the side with the gold S-100 edge connectors. Right and left assume a view from the component side of the board which has the silk screen legend.

All IC sockets will either have their pins numbered or have a 45 degree angle across the corner of pin one. On the Disk Jockey, all sockets and all IC's have pin 1 closest to the bottom right corner of the board.

## Assembly Instructions

The tantalum capacitors are polarized. The dipped tantalum cap has a red dot at its positive lead. This lead should be inserted at the bottom of the oval legend where the "+" sign is located. The 1.8 microfarad capacitor's positive lead is identified by a circular "tit" where it enters the body of the housing. The positive end of the 39 microfarad capacitors is identified by a red band. The silk screen identifies the positive lead of these axial parts with a "+" sign. The by-pass caps, identified on the silk screened legend by an asterisk "\*" enclosed by an oval, are not polarized. The .01 mylar cap and the .001 disk cap are not polarized.

The two DIP switch arrays are to be positioned so that switch paddle number 1 is toward the top of the board.

The SIP resistor packs, historically prone to being inserted backwards, should have their white dot nearest the white dot on their respective legends. This turns out to be down for the two 3.3k Ohm packs at the bottom of the board and to the right for the 180 Ohm pack just below the J1 connector at the top right of the board.

The crystals included in this kit have a piece of foam pad attached to their PC board side. When these parts are installed, the protective paper on the back of the pad should be peeled off just before the leads are inserted through the circuit board at the position indicated on the parts legend. The foam pad has an adhesive on it which will hold the crystal to the circuit board. The pad and the adhesive are insulators so that no short circuit can occur when the crystal is installed.

The orientation of the transistors is indicated on the silk screen legend of the circuit board, as is their type number. A very common cause of smoke on power-up is a 2N3906 correctly oriented in the place of a 2N3904 and vice versa.

The black band at one end of the diodes marks the cathode and should correspond to the white arrow point on the legend of the circuit board.

Placing the 50 pin flat cable connector, J1, upside down is a disaster. The angled pins should go through the circuit board. Only the longer straight pins are long enough to accept the ribbon cable to the disk drive. The I/O connector, J2, should be positioned so that the longer angled pins point toward the top of the board while the shorter straight pins go through the circuit board.

## Assembly Instructions

### EXAMINE THE BOARD

Visually examine the circuit board for any trace opens or shorts. A concentrated five minute scrutiny will uncover most trace defects. Several hours of scattered, unconcentrated scrutiny generally won't reveal anything. Take special care that no shorts or opens exist on those areas of the circuit board that will be covered by IC sockets. Ohm out any suspicious looking traces for either shorts or discontinuity as appropriate. Return immediately any bare board found to be flawed. Such boards will be replaced under warranty.

### SOLDERING AND SOLDER IRONS

The most desirable soldering tool for complex electronic kits is a constant temperature iron with an element regulated at 650 degrees F. The tip should be fine so that it can be brought into close contact with the pads of the circuit board. Such irons are available from Weller and Unger and should be part of any electronics shop.

There are three important soldering requirements for building this kit:

1. Do not use an iron that is too cold (less than 600 degrees F) or too hot (more than 750 degrees F).
2. Do not hold the iron against a pad for more than about six seconds.
3. Do not apply excessive amounts of solder.

The recommended procedure for soldering components to the circuit board is as follows:

1. Bring the iron in contact with BOTH the component lead AND the pad.
  2. Apply a SMALL amount of solder at the point where the iron, component lead, and pad ALL make contact.
  3. After the initial application of solder has been accomplished with the solder flowing to the pad and component lead, the heat of the iron will have transferred to BOTH the pad AND lead. Apply a small amount of additional solder to cover the joint between the pad and the lead.
- DO NOT PILE SOLDER ON THE JOINT! EXCESSIVE HEAT AND SOLDER CAUSE PADS AND LEADS TO LIFT FROM THE CIRCUIT BOARD. EXCESSIVE SOLDER IS THE PRIMARY CAUSE FOR BOARD SHORTS AND BRIDGED CONNECTIONS.

## PARTS INSTALLATION

[ ] Install and solder the four signal diodes (1N914 or equivalent) and clip the excess leads from the parts. Be sure that the black bands of the diodes are positioned to match the arrow points of the white legend of the circuit board

PROTECT YOUR EYES WHEN YOU CLIP COMPONENT LEADS AFTER SOLDERING

[ ] Install and solder all the 1/4 watt resistors in place. Do this in sections so that the leads can be conveniently clipped.

[ ] Install, solder, and trim the leads of the 1% precision resistors.

[ ] Install, solder, and trim the lead of the 1N751A Zener diode. Be sure that the black band of the diode is to the left as indicated by the white arrow point.

[ ] Next, install, solder and trim the leads of the 750 Ohm 1/2 watt resistors.

[ ] Install and solder the 40 pin sockets first, then the 20, 18, 16, and 14 pin sockets in that order. Finally install and solder the 8 pin socket. By installing the sockets in this order, a smaller sized socket will never be placed in a larger sized position.

[ ] Install and solder the SIP resistor pack arrays. The top pack should have its white dot to the right while the bottom packs will have their white orientation dots to the bottom of the circuit board.

[ ] Install and solder the 5 axial lead 1.8 microfarad capacitors. The top two have their "+" leads to the right while the bottom three have their "+" leads to the left. Clip the excess leads from the parts.

[ ] Install, solder, and clip the leads of the two 39 microfarad caps. The red band of these parts must point to the right.

[ ] Bend the leads of the 7812 and 7912 regulators, skipping the 7805's for now. Placing a nut on top of the regulator, insert a screw from the bottom of the circuit board through the hole of the board and through the hole of the regulator. Hand tighten the nut. Solder the leads. Tighten the screws firmly.

## Parts Installation

[ ] After bending the leads 90 degrees, install and solder the two crystals in place. Clip the excess leads. Fix them to the circuit board by peeling the protective paper off their foam pad and pressing the pad against the board. Be sure to solder the crystals into place so that their padded side will fall into the area outlined on the silk screened legend.

[ ] Install and solder the two connectors J1 and J2. Be sure to reread the orientation section before installing these parts.

[ ] Install and solder the light emitting diode at the top of the board just to the right of J2. One of the leads of this diode is longer than the other. The longer lead is the anode and must be to the left when the part is inserted. Clip the excess leads after soldering.

[ ] Install, solder and clip the leads of the 1.5 dipped tantalum cap just below J2. Be sure that the lead with the red dot is pointed toward the bottom of the circuit board.

[ ] Install, solder and clip the 33 picofarad silver mica cap just to the left of the 10 Meg crystal in the upper left corner of the board.

[ ] Install, solder and clip the two 47 picofarad silver mica caps above and below the 74221 IC at location 4B.

[ ] Install, solder and clip the two 33 picofarad silver mica caps-- one below the 74LS165 IC at location 2D and the other between the 74LS244 IC (labeled 74LS240 on the silk screened legend) at 6D and the 74LS367 at 7D.

[ ] Install, solder and clip the 112 picofarad silver mica cap beneath the 74221 IC at location 6B.

[ ] Install, solder and clip the 470 picofarad mica cap beneath the 7404 IC at location 6B.

[ ] Install, solder and clip the .001 microfarad disk cap to the left of the 74LS74 IC at location 6A.

[ ] Install, solder and clip the .01 microfarad mylar cap to the left of the 1458/4558 IC at location 4A.

[ ] Install, solder and clip the leads of the three transistors near J2, and of the 3904 transistor below DIP switch 4D, carefully observing the placement and orientation information silk screened on the circuit board.

[ ] Install and solder the two DIP switch arrays. Switch 1 of each DIP should be positioned toward the top of the board.

## Parts Installation

[ ] Install, solder, and clip the leads of the 19 by-pass capacitors whose positions are identified by an oval with an asterisk "\*" in the middle.

[ ] Bend the leads of the two 7805 regulators and insert them in the circuit board. Place a separate, finned heat sink between the regulator and the board, work a screw from the back of the board through the board, heat sink, and regulator and hand tighten into the nut on top of the regulator. Solder the leads and adjust the wings of the separate heat sink and, finally, tighten the screw.

## CLEAN AND EXAMINE THE BOARD

Use flux cleaner to remove solder rosin residue. Examine the circuit board carefully for shorts, solder bridges, or missed pins.

## HOW TO FIND WHERE TO PLACE PARTS

For parts placement, please see the silk screened legend on the printed circuit board.

When placing IC's in their sockets (which you should NOT do at this time!), be aware of the following deviations from or options to the IC numbers marked on the silk screened legend:

--Where the silk screened legend calls for a "6.19" K resistor, use a 5.36K precision resistor.

--Where the silk screened legend calls for a "13.0" K resistor, use an 11.0K precision resistor.

--Though the silk screened legend says "100P" for the lower two silver mica caps, 33 picofarad caps should be used at these two locations.

--Though the silk screened legend says "LS240" at 5D and 6D, 74LS244's may also be used here. Only 240's should be used at 9D and 10D.

--Only a 7404 should be placed in location B3, as indicated in the legend. An "LS" part, either a 74LS04 or a 74LS14, must not be substituted.

--Location 3C, which is marked "LS00", should have a 74LS132-- NOT a 74LS00.

With the exception of those parts listed above, IC's may vary from those marked on the silk screened legend if they are listed as alternate IC's (following a slash) in the Parts List on pages 29-31.

Parts Installation

DO NOT INSERT ANY IC'S IN THEIR SOCKETS AT THIS TIME

## Parts Installation

### INITIAL CHECK-OUT AND POWER-UP

Before inserting any IC's in their sockets perform the following check-out procedure:

1. Re-check the back of the board for solder shorts and bridged connections and for pins of IC sockets that have not been soldered. These unsoldered pins can cause aggravating intermittent problems during check-out.

2. Re-check components for orientation and make sure all components to be soldered have been soldered.

3. With an ohm meter, check for shorts between all regulated voltages (+5V, -5V, +12V, -12V) and ground and between any two regulator outputs (all regulator output pins are on the right side of the regulator, towards the bottom of the circuit board in this case). Check for shorts between S-100 supply voltages (+8V, +16V, -16V) and ground. S-100 pins 1 and 51 hold 8 volts, pin 2 holds +16 volts, and pin 52 -16 volts. Ground is on S-100 pins 50 and 100. Check these voltages for shorts among each other.

4. Place the board WITHOUT IC's into an empty system bus slot and power up. In case of smoke, power down immediately and investigate.

5. With a VOM or scope, check the regulators for +5V (both of the 7805's), +12V, and -12V. The bottom pin of all four regulators is the output. Check for Vcc and ground on all IC's. Check for +12V on the 1791 controller, the 2941 baud rate generator, and the 1458/4558 op amp. Check for -12V on the 1602 UART and the 1458/4558 op amp. Finally, check for -5V on the 2941 baud rate generator. If everything is OK, power down and proceed to the next step.

### IC INSERTION

If an IC insertion tool is not available, IC leads should be straightened a ROW at a time, not by the individual PIN. The edge of a straight sided table is an excellent device for this operation. Hold the IC by the plastic case, place one row of legs against a flat surface and push very slightly. Repeat with the opposite row. Continue this procedure until the legs of the IC can be inserted with minimum effort into its socket.

When inserting an IC into its socket, take care that you DO NOT BEND THE IC'S LEGS UNDERNEATH ITS PLASTIC PACK. This is an extremely common error and can escape even a fairly careful visual inspection.

## Parts Installation

If IC pins become bent under during insertion, use a long nose pliers to straighten them and try again. When removing an IC from its socket, use an IC remover, an IC test clip (another must for any electronics shop) or a miniature screw driver. DO NOT ATTEMPT TO REMOVE AN IC WITH YOUR FINGERS. You will bleed on severely bent pins.

Once all IC's have been inserted, re-check for bent pins. Then check twice for proper orientation. Upside down IC's are generally destroyed upon power up.

IF FOR ANY REASON IT BECOMES NECESSARY TO REMOVE A COMPONENT WHICH HAS BEEN SOLDERED TO THE CIRCUIT BOARD, CLIP ALL LEADS BEFORE REMOVING. THIS WILL REDUCE THE CHANCE OF LIFTING PADS OFF TRACES.

## POWER UP

If all previous checks have been performed, you are ready to put power to your fully populated board. In an empty system with power off, insert the Disk Jockey and power up. If the board smokes, power down and investigate. If not, measure the regulated voltages again.

If any voltages have been lost since powering up the bare board, power down and check for upside down IC's. Isolate the possible faulty chip or chips by powering down, removing a section of IC's, and powering up again. Continue this sequence until the faulty IC or IC's are found.

BE SURE NEVER TO INSERT OR REMOVE A BOARD WITH POWER ON! THIS MAY DAMAGE THE BOARD

This completes the initial check-out of your Disk Jockey.

FIELD ENGINEERING MEMO

TO: All DISCUS Owners and Dealers

SUBJECT: Update for DISCUS Double Density Operating Systems

FROM: George Morrow

In a world of sell-and-forget, you may be gratified to learn that Morrow Designs sells and remembers. That's why we're offering an operating systems upgrade for all DISCUS Double Density Disk Drives. At cost. Or below.

Here's why: We found an anomaly in Western Digital's 1791 Floppy Disk Controller chip. Nothing major.

But under certain conditions, you could get an "error" from CP/M<sup>®</sup> Operating System (BDOS ERROR - "BAD SECTOR"). When this happens, certain information on the disk is no longer readable. But it's software correctible. So, we're correcting it. At cost. Or below.

Here's what you do:

For the Double Density DISCUS Controller Model B

- a) If the 2708 EPROM has a label marked "B/V2", no action is required -- you have the latest version of the driver software which corrects the 1791 anomaly.
- b) If the 2708 EPROM has no label, it must be replaced or reprogrammed: Send us a check for \$15.00 or a 2708 EPROM which is erased and functional.

For the Double Density DISCUS Controller REVs 0, 1, 3 and 4

- a) If you have 2.0, 2.1, or 2.2 CP/M, send us a clean diskette or your check for \$7.00. We'll send back the latest 2.2 CP/M diskette. (Remember to include the serial number with your reply.)
- b) If you have Lifeboat 1.4 CP/M, it's going to be a little more expensive. \$42.00. For that we'll send you the latest version of CP/M 2.2 on a diskette and complete documentation for the upgrade. Or, if you send us a clean diskette, the cost is only \$35.00. Normally, the cost of the documentation alone is \$35.00. Again, we must have the serial number of your CP/M in order to make this upgrade.

CBIOS  
Ver 3.0  
15 01c

## NOTES ON LIFEBOAT 2D CP/M FOR THINKER TOYS

There are several features of Lifeboat's 2D version of CP/M with which users accustomed to single density CP/M on 8 inch drives may not be familiar. These features will be explained below.

### ASSIGNING DENSITY

2D CP/M must be aware of the density of a diskette before it can successfully perform a read or write operation. The command file "DENSITY" allows the user to inform CP/M of the density which a given drive will be assigned. If a wrong density diskette is placed in a drive, and that drive is subsequently accessed, the system will fall into an irrecoverable error.

The default assignment of densities in the production CP/M disk is: A, C, and D drives = Double Density; B drive = Single Density

To change this arrangement temporarily, type DENSITY and follow the prompts. To make a permanent change, follow the instructions contained in the "ASM" file TTUSER.

### FORMATTING A DISKETTE

The two command programs, FORMAT1D and FORMAT2D, will format a diskette in single and dual density respectively. FORMAT1D will write sector headers for 26 sectors per track, 128 bytes per sector. FORMAT2D will write sector headers for 26 sectors per track, 256 bytes per sector. A disk can be formatted in either density regardless of the density assigned to the formatting drive under CP/M-- however the drive will not be able to read the disk it has just formatted unless the drive has been assigned the proper density.

### USER and TTUSER

2D CP/M dedicates the equivalent of three single density sectors, or one and a half pages of memory, for user I/O. In single density CP/M this was subsumed under the CBIOS. In a 24K system, locations 5E80 to 5FFF contain user I/O.

To alter CP/M size or change the I/O routines or both from the original production configuration, the USER or TTUSER file must be edited to reflect the desired changes and re-assembled to create a HEX file of the new I/O. The active I/O on production diskettes was assembled from the file called TTUSER, while a simpler file called USER provides an alternative specimen which does not implement I/O byte.

Both source files are amply commented. It should be noted that to retain the file TTUSER as the actual I/O driver after a MOVCPM command, only the EQUATE labeled "MSIZE" need be changed in the edit prior to re-assembly. However, after re-assembly, the PRN file of TTUSER should be examined in order to find the new "OFFSET" variable which will be needed in order to overlay the driver onto the new CP/M system.

A simple MOVCPM N command will create a new CP/M of "N" K size with only the console driver implemented. Thus no overlay is necessary if the only device CP/M is to be aware of is the console terminal.

#### RECONFIGURING A SYSTEM

Once the USER or TTUSER file has been edited and re-assembled, the following procedure may be used to incorporate the new drivers into CP/M:

- Note the OFFSET of the new CP/M from the PRN file of USER or TTUSER.
- Type "MOVCPM N \*", where N represents the memory size in kilobytes. The smallest CP/M size is 17K.
- Type "SAVE 35 CPMN.COM", with N as above.
- Type "DDT CPMN.COM", with N as above.
- Type "IUSER.HEX", or "ITTUSER.HEX"
- Type "ROFFSET", where OFFSET is the value obtained from the PRN file USER or TTUSER. For a 24K system, one would type "RC380; for a 32K system, RA380 etc. 6380 14PK
- Type control C
- Type "SYSGEN"; CP/M will request for the source drive.
- Type Return; the source for the new system is already in memory.
- Type the destination drive-- A,B,C or D. Make sure that the drive in question has a disk formatted in the proper density.
- Reset the system and boot the new disk.

#### SAVEUSER

The SAVEUSER command places whatever I/O that happens to be in memory onto the CP/M boot program. Thus new I/O drivers can be patched in from a front panel or monitor, and made permanent through the SAVEUSER command. A subsequent MOVCPM command will overwrite this patch, so once a driver has been tested it should be incorporated into a USER source file as soon as possible. The memory locations to patch in I/O drivers can be found in the listing of TTUSER included with the CP/M diskette.

#### AUTO.COM

The AUTO.COM function does not work at this time.
