XDS 930 Computer

## I. GENERAL DESCRIPTION

## INTRODUCTION

The XDS 930 is a high-speed, low-cost, general-purpose digital computer with the following characteristics:

- 24-bit word plus parity bit
- Binary arithmetic
- Single address instructions with

Index Register
Indirect Addressing
Programmed Operators

- Basic core memory 4,096 words, expandable to 32,768 words, all addressable with
0.7 microsecond access time
1.75 microsecond cycle time
- Memory overlap between Central Processor and I/O with two memory banks
- Memory available in 4, 8, and 16 K banks
- Multi-precision programming facility
- Typical execution times (including memory access and indexing)

Fixed-Point Operations (in microseconds)

| Add | 3.5 |
| :--- | :--- |
| Multiply | 7.0 |

Floating-Point Operations (in microseconds)

$$
\begin{array}{lcc} 
& \begin{array}{c}
\text { 24-bit Fraction } \\
\text { (plus 9-bit Exponent) }
\end{array} & \begin{array}{c}
\text { 39-bit Fraction } \\
\text { (plus9-bit Exponent) }
\end{array} \\
\cline { 2 - 3 } \text { Add } & 77 & 92 \\
\text { Multiply } & 54 & 147
\end{array}
$$

- Program interchangeability with other XDS 900 Series Computers
- Parity checking of all memory and input/output operations
- Priority Interrupt System

XDS I/O Options Interrupts 2 levels standard, 38 optional

System Interrupts, 896 optional

- Optional power fail-safe feature permits saving contents of memory and programmable registers in case of power failure.
- Up to four I/O communication channels (with optional interlacing capability), time-multiplexed with computer operation, providing input/output rates of up to one word per 3.5 microseconds
- An optional Direct Memory Access System that allows input/output transfer to occur simultaneously with computer memory access, providing input/output rates of up to one word per 1.75 mic roseconds
- One to four Direct Access Communication Channels that incorporate the Direct Memory Access System
- Data Multiplex Channel that uses direct memory access connection and accepts/transmits information from external devices, or subchannels, which may operate simultaneously; thus, externally controlled and sequenced equipment may perform input/output buffering and control operations rather than the computer.
- Time-Multiplexed Input/Output Channels operate upon either words or characters. A 6-bit character is the standard character size; 6-and 12-bit characters, or 6-, 12-, and 24-bit characters can be specified as desired. Direct Access Channels operate upon words and characters. These channels accept 6-, 8-, 12-, and 24-bit characters. The number of characters per word is specified by the external device.
- Input/output with Scatter-Read and Gather-Write facility
- Standard input/output

Time-Multiplexed Communication Channel (without interlace)

Control Console
Automatic typewriter

- Optional input/output devices

Photoelectric paper-tape reader and paper-tape punch, and spooler mounted on cart

MAGPAK Magnetic Tape System
Magnetic-tape units (IBM-compatible; binary and BCD)

Punched-card equipment
Line printers, graph plotters
Typewriter with electromechanical paper-tape reader and punch, auxiliary magnetic-drum files, disc files

* W-Buffer Standard; W Channel optional

Figure 1-1. XDS 930 Computer Configuration

Communications equipment, teletype consoles, display oscilloscopes
A/D converters, digital multiplexer equipment, and other special system equipment

- FORTRAN II and symbolic assembler as part of complete software package
- All-silicon semiconductors
- Operating temperature range: $10^{\circ}$ to $40^{\circ} \mathrm{C}$
- Dimensions: 124 inches $\times 25-1 / 2$ inches $\times 65$ inches
- Power: 3 kva

## XDS 930 REGISTERS

The 930 Central Processor contains the following arithmetic and control registers. They are full-word, 24-bit registers except as noted.

## AVAILABLE TO THE PROGRAMMER (see Fig. 1-2, dark lines)

The A Register is the main accumulator of the computer. The B Register is an extension of the A Register. The B Register contains the less significant portion of double-length numbers.
The Index Register, $X$, used in address modification, is a fullword register. Indexing operations occur only with the least significant 14 bits.

The P Register is a 14-bit register that contains the memory address of the current instruction. Unless modified by the program, the contents of $P$ increase by one at the completion of each instruction.

The Memory Extension Registers, EM3 and EM2, are 3-bit registers that specify the portion of extended memory being used.

NOT AVAILABLE TO THE PROGRAMMER (see Fig. 1-2, light lines)

The $S$ Register is a 14-bit register that contains the address of the memory location to be accessed for instructions or data. The address is augmented by one of the Memory Extension Registers.

The C Register is an arithmetic and control register used in multiply, divide, and other operations. All instructions come from memory to the C Registerbefore decoding. Address modification and parity generation/detection take place in the $C$ Register.

The $O$ Register is a 7-bit register that contains the instruction code of the instruction being executed.

The M Register is a 24-bit register that holds each word as it comes from memory. Recopying of a word into memory takes place from the $M$ Register.

Figure 1-2. Basic Register Flow Diagram

## XDS 930 MEMORY

Core memory is expandable from 4,096 to 32,768 words. Word ${ }^{\text {. }}$ length is 24 bits plus parity. The address field in the instruction format is 14 bits long, allowing direct access of up to 16,384 words. The Memory Extension System provides direct access to the total 32,768 words.

Memory is available in 4,096-, 8,192-, and 16,384-word banks.
As an optional feature, if a power loss is detected, the computer may be interrupted and the transient, programmable registers stored to provide complete fail-safe capability. With this option, power failure causes no loss of information.

Even parity is automatically generated or checked during each read/write cycle. A control panel switch may be set to halt the computer automatically in case of parity error detection.

The memory is cyclic, or "wrap-around", for each 16,384 words being addressed. An attempt to access from a location whose address is greater than that available results in an access of all zeros. An attempt to store into such a location results in a "no-op" operation, with the next instruction in sequence being executed.

## MEMORY EXTENSION SYSTEM

The Memory Extension System, containing two memory extension registers, allows addressing of memories greater than 16,384 words. The program loads either or both of the Extend Memory Registers and activates them as desired. Each register contains 3 bits, or one octal digit, that can become the most significant, or fifth, digit of any operand address.

The program uses the first extension register, EM3, by calling for an address with a 1, 1 in the most and next most significant address bits, respectively (a " 3 " for the most significant octal digit). The program calls for EM2, the second extension register, by setting the same two address bits to 1,0 (a " 2 " for the mostsignificantoctal digit). Via memory extension instructions, the program can set each of the registers to a desired "5th digit" and can test the current setting of each register. Once set, the contents of either register remain set until changed by program or by pressing the START button.

The program always addresses the first 8,192 words of core, 00000-17777, directly without regard to the Extend Memory Registers. Whenever the operator initializes the computer (presses START), the computer presets a 3 in EM3 and a 2 in EM2. This allows the programmer to address the first 16,384 words of core, 00000-37777, without being concerned with the extension system.

Example 1. By previously setting EM2 to 4, the program adds the contents of location 43300 to the A Register by executing ADD 23300. The " 2 " calls for register EM2:

Example 2. EM3 setting is 5; EM2 setting is 7:

When (EM3) $\neq 3$, the computer lights the EM3 light on the control panel. When (EM2) $\neq 2$, the computer lights the EM2 light on the control panel. When executing the MARK PLACE AND BRANCH (BRM) instruction, the computer records the contents of EM3, EM2, and the Overflow Indicator in the mark location. BRM stores overflow in bit 0 of the mark; it stores the contents of EM3 in bits 3 through 5 and the contents of EM2 in bits 6 through 8. Bits 1 and 2 are unpredictable; bit 9 is zero.

## Memory Write Lock-Out Feature (Optional)

Permanent memory protection for selected areas of memory in the XDS 930 Computer is provided by a memory lock-out feature, which is controlled either manually by switches or by the program with a lock-out register, protects the contents of memory from inadvertent destruction by operating programs.
The entire memory is divided into 2048 word blocks. Tihis first block, from 0000 to 2047, is further divided into four subblocks of 512 words each. Each of these blocks can be individually protected by turning on the appropriate switch with the manualcontrolled option or placing a one in the appropriate position of the lock-out register with the program-controlled option.
Read operations are always allowed, but if a program or I/O channel attempts to store or write into a protected block of memory, an internal interrupt occurs to octal location 35 . The memory cell referenced is not altered. Therefore, not only is memory protected, but also the supervisory program is notified that an attempt to write into an interlocked area has occurred.

## MEMORY WORD FORMATS

A computer word is 24 binary digits (bits) long.

The format above numbers the bits from the left, or most significant end of the word, to the right, or least significant end of the word. This numbering format is the basis of references to bit positions or bit numbers. Octal notation most easily describes the contents of the 24 bits of a word. Thus, one octal digit, 0 through 7, represents three binary digits. For example, the octal number, 01234567, represents its binary equivalent, 000001010011100101110111.

The computer instruction word format is:

Bit position 0 contains the Relative Address Bit. Standard loading programs use this bit; central processor decoding logic does not use or sense this bit. A l-bit (octal value of 4) in this position causes some standard loading programs to add the assigned location of the instruction to the address field contents prior to actual storage into the assigned location.

Bit position 1 (octal value of 2) contains the Index Register Bit.

Bitpositions 2 through 8 contain the Instruction Code Field which determines the operation to be performed. The Programmed Operator facility uses bit position 2 (octal value of 1 ); it is part of the "Tag" Field (bit positions 0-2).

Bit position 9 (octal value of 4) contains the Indirect Address Bit.
Bitposition 10 (octal value of 2) contains the Memory Extension Bit that controls addressing above location 8,191. A 1-bit in this position activates the memory extension logic.
Bit positions 10 through 23 contain the Address Field which usually represents the location of the operand called for by the instruction code.

The following examples use standard assembler format in expressing instructions. This format is:

LDA 1000,T
where:
LDA is a representative mnemonic instruction code, 1000 is a representative address that is written decimally, and $T$ is a $I$-digit octal integer that represents the Tag Field.

To express indirect addressing (that is, a "one" in the Indirect Address position), the programmer prefixes an asterisk to the address field:

$$
\text { LDA * } 1000, \mathrm{~T}
$$

The interpretation of the Tag Field (bit positions 0-2) integer, $T$, when required, is composed of the sum of the octal values of its constituents; it is written as follows:

| Tag Field Integer T | Interpretation |
| :---: | :---: |
| 0 (or blank) | No Relative Address, No Index, No Programmed Operator |
| 1 | Programmed Operator |
| 2 | Index |
| 3 | Programmed Operator and Index |
| 4 | Relative Address |
| 5 | Programmed Operator and Relative Address |
| 6 | Both Relative Address and Index |
| 7 | Programmed Operator, Index, and Relative Address |

Tag Fields of $1,3,5,7$ are usually replaced by a specific Programmed Operator mnemonic along with Tag Fields of $0,2,4,6$, respectively.

In the explanation of specific instructions, the format used for the instruction word is:

where $R, X$, and $I$ are as defined previously, 000 represents the instruction, and $M$ represents a generalized memory address.

FIXED-POINT FORMAT
Fixed-point data words have the format:

Numbers held in this format are 8-digit, octal numbers, with the sign incorporated as the "leading bit" in the most significant octal digit. Bit position 0 is the sign bit, with negative numbers having a " 1 " in bit position 0 and positive numbers having a " 0 " in bit position 0.

The memory holds fixed-point numbers as 23-bit fractions with an assumed binary point to the left of bit position one. Numbers held in one word have the equivalent precision of over six decimal digits. The range of values of the fixed-point format is from minus one to slightly less than plus one. Scaling is used in handling numbers during computation.

Programmers sometime consider fixed-point numbers to be integers, with the binary point to the right of bit position 23. The range of integer values is from $-2^{23}$ to $+2^{23}-1$.

The memory holds negative, fixed-point numbers in two's complement form; the computer operates on these numbers arithmetically in a two's complement number system. See Appendix A-10 for a discussion of two's complement arithmetic.

## FLOATING-POINT FORMAT

XDS offers standard programmed operator packages for performing double and single-precision floating-point arithmetic. The following paragraphs explain the standard floating-point number formats.

## Double Precision Floating-Point Format

The fractional portion of a double precision, floating-point number is a 39 -bit, proper fraction, with the leading bit being the sign bit and the assumed binary point just to the left of the most significant magnitude bit (bit 1 of the upper word).
The floating-point exponent is a 9-bit integer, with the leading bit being the sign. The standard routines operate on both fraction and exponent in two's complement form. If F represents the contents of the fractional field and E represents the contents of the exponent field, the number has the form $F \times 2^{E}$.

Double precision, floating-point numbers have over 11 decimal digits of precision and a decimally equivalent exponent range of $10^{-77}$ to $10^{+77}$.

Standard Programmed Operators assume that the more significant word is in the A Register, or stored in memory location $M+1$, and that the less significant word is in the B Register, or stored in memory location $M$.

## Single Precision Floating-Point Format

Fractional Word

The fractional portion of a single precision, floating-point number is a 24-bit proper fraction, with the leading bit being the sign and the assumed binary point just to the left of the most significant magnitude bit. The floating-point exponent is a 9-bit integer with a leading sign bit. The standard routines operate on both fraction and exponent in two's complement form.

Single precision, floating-point numbers have over six decimal digits of precision and a decimally equivalent exponent range of $10^{-77}$ to $10^{+77}$.

Standard Programmed Operators assume that the fractional word is in $A$, or stored in memory location $M+1$, and that the exponent word is in B, or stored in memory location M. When entering a standard Programmed Operator routine, bits 0-14 of the exponent word are ignored.

## SPECIAL CHARACTERISTICS

Certain computer features simplify programming and provide significant economies in memory and in program running time.

## ADDRESS MODIFICATION

Indexing and indirect addressing, used singly or in combination, perform address modification. In both indexing and indirect addressing, the computer performs address modification after bringing the instruction from memory but before executing it. The instruction remains in memory in its original form. The results of indexing and/or indirect addressing form the "effective address".

## INDEXING

The computer contains an Index Register for address modification The use of this register to modify the address in an instruction does not increase instruction execution time.

If the content of the Index Bit in an instruction is a "one", the computer adds the contents of bits 10 through 23 of the $X$ Register to the contents of the Address Field of the instruction prior to execution. This addition does not keep any overflow or carry beyond the fourteenth address bit.

The instruction set provides instructions for modifying and testing the X Register, and for transferring information between the $X$ and $B$ Registers, the $X$ and $A$ Registers, and the $X$ Register and memory.

## INDIRECT ADDRESSING

The Indirect Address Bit is in bit position 9 of the instruction. This bit determines whether the computer uses indirect addressing with the instruction being executed.

A zero in the Indirect Address Bit causes the computer to use the contents of the Address Field (bit positions 10-23 in the instruction) as the 5 -digit, octal address requested by the instruction. A one in the Index Bit causes the computer to add the contents of the Index Register to this address to form the effective address.

A one in the Indirect Address Bit causes the computer to decode the contents of the effective address, accessed as described above, as if it were an instruction without an instruction code; that is, the address logic reinitiates address decoding, using the word in the effective location (the memory cell whose address is the effective address). This is an iterative process and provides multi-level indirect addressing. Indirect addressing adds one cycle time to instruction execution time for each level of addressing. The programmer can use indexing to modify indirect addressing at every level.

## EXAMPLES: INDEXING AND INDIRECT ADDRESSING

The octal instruction code for LOAD A REGISTER (LDA), used in the examples, is 76 .

| Location | Contents | Effect |
| :---: | :---: | :---: |
| X | 00000001 |  |

| 2002 | 07641000 | $((1000))=(1001)=00041002 \rightarrow A$ |
| 2003 | 27641000 | $((1000+1))=((1001))=(41002)=$ |
|  |  | $((1002))=(1003)=00000002 \rightarrow A$ |

## Nomenclature

When discussing properties of the various instructions, including the indirect addressing facility, several terms describe specific locations or addresses.

The term "effective memory location" describes the location in memory from which the final operand is taken at the conclusion of all indirect addressing and indexing. This term is sometimes shortened to "effective location." It is the location whose address is the effective address.

The term "effective operand" means the contents of the effective memory location.

## PROGRAMMED OPERATORS

Programmed Operators (called POP) permit the calling of subroutines with a single instruction of the same form as built-in machine instructions. The computer decodes the codes $100_{8}-177_{8}$ as special instructions and transfers to a subroutine uniquely determined by the code. The computer records the address of the POP instruction at location 00000 together with an indirect address bit so that the program continuity may be maintained. By indirect addressing which refers to location 00000, which in turn refers to the POP instruction, the subroutine can gain access to the effective address of the operand assoc iated with the POP instruction.

Programmed Operator subroutines are assigned three-letter, mnemonic designations in the same manner as built-in, machine instructions described in Section II. A program can use up to 64 Programmed Operators at any one time; however, since Programmed Operators are programmer-specified, the programmer can select alternate sets or sub-sets of the 64 Programmed Operators from program to program or from section to section of the same program. The total number of Programmed Operators is without limit; but it is inconvenient to use more than 64 in one program. Other computers in the XDS 900 Series maintain symbolic homogeneity through use of Programmed Operators. Mnemonic designations are identical in all computers. For example, while the designation "FLA" (for Floating ADD) may refer to a built-in, machine instruction in one computer, it refers to a Programmed Operator subroutine in another. This technique preserves the one-to-one instruction relationship; programs written for one 900 Series Computer can run on any other computer in the series.

A more detailed discussion and a list of standard XDS Programmed Operator routines are in Appendix A-17.

## OVERFLOW

The Overflow Indicator in the computer permits the detection of erroneous arithmetic operations that occur during the execution of a program. The Overflow Indicator turns on if any of the following occur:

A sum or difference resulting from an addition or subtraction that cannot be contained within the A Register.

Multiplication of $N$ by $N$ where $N$ is 40000000 , the largest negative number that can be represented in an XDS 930 word. The A and B Registers cannot contain this product.

A division operation where the absolute value of the numerator is equal to (positive result) or larger than the absolute value of the denominator. The A Register cannot contain this quotient.

A left-shift operation that shifts a bit of absolute magnitude equal to one beyond position 1 of the A Register.

The instruction set (see Section II) contains instructions to reset, or test and reset the state of the Overflow Indicator.

The only instruction whose execution is altered by the state of the Overflow Indicator is OVERFLOW TEST (OVT), which skips if overflow is reset. Thus, the state of the Overflow Indicator can be ignored if desired. This is unlike some machines in which overflow causes a trap or halt.

To determine whether a particular instruction causes overflow, turn off the Overflow Indicator before executing the instruction. An instruction that may be used to turn on overflow is BRR. The instruction A BRR A, 4 "branches" to the next location and turns on the Overflow Indicator.

If the Overflow Indicator is on, it remains on until the appropriate instruction turns it off.

The execution of Programmed Operator, closed and interrupt subroutines automatically preserves the status of the Overflow Indicator. In the execution of a Programmed Operator instruction, the computer automatically places the status of the Overflow Indicator in bit position 0 of location 00000 and resets the Overflow Indicator. The instruction, MARK PLACE AND BRANCH (BRM), places the status of the Overflow Indicator in bit position 0 of the effective memory location and does not disturb the Overflow Indicator.

The instruction, RETURN BRANCH (BRR), automatically merges the contents of the Overflow Indicator with the contents of bit position 0 of the effective memory location and places the result in the Overflow Indicator. Section II contains a description of the above branch instructions.

## SUBROUTINE EXECUTION

The XDS 930 Computer provides three distinct methods of subroutine execution :

Normal closed subroutine where the input parameters are specified in appropriate registers such as the A Register

Interrupt subroutine that is entered as the result of an interrupt

Programmed Operator subroutine.

A program enters a normal closed subroutine via a MARK PLACE AND BRANCH (BRM) instruction; BRM automatically stores the contents of the Program Counter ( $P$ ) Register and the status of EM3, EM2, and Overflow Indicator in the branch-to location. $P$ Register value is the address of the BRM instruction. A RETURN BRANCH (BRR) instruction accomplishes the return to the main program; the $B R R$ adds one to the stored P Register value and transfers control to that location. See Section II, Branch Group, for a description of the branch instructions.

Interrupt subroutines are closed subroutines that are initiated by the detection of program-controlling interrupts that automatically cause the specific interrupt subroutine to be entered. A BRM instruction enters an interrupt subroutine; the BRM automatically stores the contents of the P Register, EM3, EM2, and Overflow Indicator in the branch-to location. The value stored from the P Register is the address of the instruction to which program control should return after the interrupt is serviced by the interrupt subroutine. A BRANCH UNCONDITIONALLY (BRU) instruction with indirect addressing returns control to the main program at the completion of the subroutine. BRU also clears the interrupt from the active state. Note that this differs from the normal closed subroutine return that uses the BRR (stored $P$ value $+1 \rightarrow P$ ). The point in an execution cycle at which the interrupt routine-entering BRM executes has al ready caused the proper incrementing to occur.

## II. MACHINE INSTRUCTIONS

## INTRODUCTION

This section describes XDS 930 instructions; the instructions are in functional groups. Lists of instructions in functional, numerical, and alphabetical order are in Appendixes A-20, $\mathrm{A}-25$, and $\mathrm{A}-29$, respectively.

The following statements apply to the instruction descriptions:
All instruction times are in memory cycles, where each cycle is 1.75 microseconds, and include accessing the instruction and all required operands.
Parentheses denote "contents of." For example, "(A)" denotes "contents of the A Register."

Indexing and Indirect Addressing apply to all instructions except as noted. Indexing does not change the instruction execution time. Each level of indirect addressing requires one additional memory cycle.

The interrupt system can interrupt the program sequence at the end of any instruction except as noted.

Each instruction description specifies the registers affected.
With the description of each instruction is a diagram representing the format of the instruction. Preceding this diagram is the mnemonic code that identifies the instruction and the name of the instruction.

EXAMPLE :

The letter $M$ represents the address part of the instruction. Some instructions have octal numbers in the address field. These instructions do not refer to memory.

## LOAD/STORE INSTRUCTIORS

LDA LOAD A

LDA loads the contents of the effective memory location into the A Register.

Registers Affected: A
Timing: 2

STA STORE A

STA stores the contents of the A Register in the effective memory location.

Registers Affected: M
Timing: 3

LDB LOAD B

LDB loads the contents of the effective memory location into the B Register.

Registers Affected: B
Timing: 2

STB STORE B

STB stores the contents of the B Register in the effective memory location.

Registers Affected: M
Timing: 3

LDX LOAD INDEX

LDX loads the entire 24-bit contents of the effective memory location into the Index Register.

Registers Affected: X
Timing: 2

STX STORE INDEX

STX stores the entire 24-bit contents of the Index Register in the effective memory location.

Registers Affected: M
Timing: 3

## EAX COPY EFFECTIVE ADDRESS INTO INDEX REGISTER

EAX copies the address of the effective memory location into the Index Register.

The addressing process for this instruction operates as in a Load A instruction, except that instead of obtaining the contents of the effective memory location, the effective memory address acts as the operand. This addressing process is sometimes called "immediate addressing." For example, if execution of this instruction occurs with a zero indirect address bit and a zero
in the index field, then the actual bit configuration in the address field of EAX copies into the Index Register.

The ten most significant bits of the Index Register are unaffected.
Registers Affected: $X_{10-23}$
Timing: 2

XMA EXCHANGE MEMORY AND A

XMA loads the contents of the effective memory location into the A Register and stores the contents of the A Register in the effective memory location.

Registers Affected: A,M
Timing: 3

## ARITHMETIC INSTRUCTIONS

## ADD ADD MEMORY TO A

This instruction adds the contents of the effective memory location to the A Register and places the result in A.

After execution, bit position 0 of the Index (X) Register contains the carry from bit position 0 of the 24-bit adder. Therefore, the programmer should be careful when attempting to hold a full word quantity in X while performing an addition.

If both numbers are of the same sign but the sign of the result is opposite, overflow has occurred and the computer has set the Overflow Indicator.

Registers Affected: A, $X_{0}$, Overflow Indicator Timing: 2
ADC ADD WITH CARRY

This instruction performs multi-precision addition. Using the instruction, ADD M TO A (55), the program adds the lower halves of the numbers first. ADD automatically retains the carry in the sign position of the $X$ Register. The program then adds the two upper halves, using $A D C . \quad A D C$ is the same as ADD M TO A (55), except that it adds the carry bit previously generated into the low-order position.

After execution, bit position 0 of the Index ( X ) Register contains the carry from bit position 0 of the 24 -bit adder. Therefore, the programmer should be careful when attempting to hold a full word quantity in X while performing an add with carry.

The computer automatically clears the Overflow Indicator prior to execution of this instruction since overflow resulting from the addition of the lower half of the multi-precision numbers is not meaningful.

If both numbers of the upper half are of the same sign but the sign of the result is opposite, an overflow has occurred and the computer sets the Overflow Indicator.

Registers Affected: $A, X_{0}$, Overflow Indicator
Timing: 2

## EXAMPLE:

Assume the $A$ and $B$ Registers contain a double precision number to which the double-precision number, 15034166 12300000, in Locations 1021 and 1020 is added. The less significant half appears in 1020.

The sign position of $B$ and the sign position of the less significant half (1020) are not considered signs but are binary digits. Thus, a double precision number in $A B$ consists of a sign ( $A_{0}$ ) and 47 binary digits $\left(A_{1}-A_{23}, B_{0}-B_{23}\right)$. The number is in two's complement form.

The program is:

| Location | Instruction | A | B | Carry |
| :---: | :---: | :---: | :---: | :---: |
| (Prior to | Execution) | 20314624 | 71510426 | - |
| 2100 | XAB | 71510426 | 20314624 | - |
| 2101 | ADD 1020 | 04010426 | 20314624 | 1 |
| 2102 | XAB | 20314624 | 04010426 | 1 |
| 2103 | ADC 1021 | 35351013 | 04010426 | 0 |

NOTE: Since the process is self-propagating, this instruction is used in performing additions of any precision. See the instruction, EXCHANGE A AND B (XAB), one of the Register Change Instructions, this section, for an explanation of its operation.

ADM ADD A TO MEMORY

ADM adds the contents of the A Register to the effective memory location and stores the result in the same location.

If both numbers are of the same sign but the sign of the result is opposite, an overflow occurs and the computer sets the Overflow Indicator. The contents of the A Register do not change.

Registers Affected: M, Overflow Indicator Timing: 3

## MIN MEMORY INCREMENT

MIN increases the contents of the effective memory location by one, and places the resulting sum in the same location. The contents of the A Register do not change.

Overflow occurs with this instruction only when the contents of $M$ are 37777777 before execution. In this case, 40000000 is the result in $M$.

Registers Affected: M, Overflow Indicator
Timing: 3

## SUB SUBTRACT MEMORY FROM A

SUB subtracts the contents of the effective memory location from the A Register and places the result in the A Register.

After execution, bit position 0 of the Index ( X ) Register contains the carry from bit position 0 of the 24 -bit adder. Therefore, the programmer should be careful when attempting to hold a full word quantity in $X$ while performing a subtraction.

If both numbers are of the same sign after the subtrahend has been complemented for addition but the sign of the result is opposite, an overflow has occurred and the computer sets the Overflow Indicator.

Registers Affected: A, $X_{0}$, Overflow Indicator Timing: 2

## SUC SUBTRACT WITH CARRY

SUBTRACT WITH CARRY is used to perform multiple-precision subtractions. The program desiring to perform a multipleprecision subtraction first uses the SUBTRACT instruction to form the low-order 24 bits of the result. The SUB instruction automatically retains the carry bit in the sign position of the $X$ register. The program then obtains the rest of the multipleprecision result by performing successive SUC instructions on the remaining portions of the multiple-precision numbers. The SUC instruction also automatically retains the carry bit in the sign position of the X register.

SUBTRACT WITH CARRY inverts (forms the one's complement of) the effective word, adds the inverted word plus the carry bit (sign position of the $X$ register) to the contents of the $A$ register, and loads the result into the $A$ register.

After execution of SUC, bit position 0 of the index $(X)$ register contains the carry from bit position 0 of the 24-bit adder. Therefore, the programmer should be careful when attempting to hold a full word quantity in $X$ while performing a SUBTRACT WITH CARRY.

The computer automatically clears the overflow indicator prior to the execution of this instruction since overflow resulting from the subtraction of the low-order portions of the numbers is not meaningful.

If the sign of the value in $A$ is equal to the sign of the inverted word but the sign of the result in $A$ is opposite, overflow has
occurred, in which case the computer sets the overflow indicator to 1 ; otherwise, the computer resets the overflow indicator to 0 .

## EXAMPLE :

Assume that Registers $A$ and $B$ and memory location $M$ contain a triple-precision number from which the triple-precision number in location $L, L+1$, and $L+2$ is subtracted. The octal numbers 361420703156700010000001 and 14236213 4612000010000000 are in the following locations:

| $\underline{A}$ | $\underline{B}$ | $\underline{M}$ |
| :---: | :---: | :---: |
| 36142070 | 31567000 | 10000001 |
|  |  |  |
| 14236213 | $\underline{L}+1$ | $\underline{L+2}$ |
|  | 46120000 | 10000000 |

The sign of one triple-precision number is in $A_{0}$, while its 71 binary digits are in $\mathrm{A}_{1-23}, \mathrm{~B}_{0-23}$, and $\mathrm{M}_{0-23}$. The sign of the other number is in $L_{0}$, and its 71 digits are in $\mathrm{L}_{1-23}$, $\mathrm{L}+\mathrm{I}_{0-23}$, and $\mathrm{L}+2_{0-23}$.

## Execution:

| Location | Instruction |  | A | B | Carry |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 2100 | XMA | M | 10000001 | 31567000 | - |
| 2101 | SUB | L + 2 | 00000001 | 31567000 | 1 |
| 2102 | XMA | M | 36142070 | 31567000 | 1 |
| 2103 | XAB |  | 31567000 | 36142070 | 1 |
| 2104 | SUC | $L+1$ | 63447000 | 36142070 | 0 |
| 2105 | XAB |  | 36142070 | 63447000 | 0 |
| 2106 | SUC | L | 21704654 | 63447000 | 1 |

Answer: 217036546344700000000001
NOTE: Since the process is self-propagating, this instruction performs subtractions of anyprecision. See EXCHANGE A AND B (XAB), under Register Change Instructions, this section, for explanation of its operation.

Registers Affected: A, $X_{0}$, Overflow Indicator Timing: 2

MUL MULTIPLY

This instruction multiplies the contents of the A Register by the contents of the effective memory location and places the product in the $A$ and $B$ Registers with the more significant portion in $A$. The sign of the product is in $A_{0}$; the bit in $B_{0}$ is part of the product, not treated as a sign bit. Since the product contains at most 46 significant bits, the content of $\mathrm{B}_{23}$ is not significant and is zero.

The original contents of $B$ do not affect the operation of the MULTIPLY instruction and are destroyed. If the contents of both the multiplier and multiplicand have the value $40000000_{8}$, overflow occurs and the computer sets the Overflow Indicator.

Registers Affected: A, B, Overflow Indicator Timing: 4

EXAMPLE: Multiplication of 3 by 3

|  | $\frac{A}{A}$ | $\frac{B}{3}$ | $\frac{\text { Memory }}{}$ |
| :--- | :---: | :---: | :---: |
| Before Execution | 00000003 | Not Meaningful | 00000003 |
| After Execution | 00000000 | 00000022 | 00000003 |

Note that $0000000000000011_{8}$ scaled at 47
is equal to $0000000000000022_{8}$ scaled at 46.

DIV
DIVIDE

This instruction divides the contents of the $A$ and $B$ Registers, treated as a double-precision number, by the contents of the effective memory location and places the quotient in the $A$ Register, with the remainder in the $B$ Register.
No overflow occurs if $-1 \leq \frac{(A, B)}{M}<1$ (if the contents of $A$ and $B$ divided by the contents of the effective location are greater than or equal to minus one but strictly less than plus one). If the quotient exceeds these boundaries, overflow occurs and the computer sets the Overflow Indicator. In this latter case, the results are not arithmetically correct. See Appendix A-19 for a further description of division.

Registers Affected: A, B, Overflow Indicator Timing: 10

EXAMPLE:
Division of 7 scaled at binary 46 by 3 at binary 23 is:

|  | A | $\underline{B}$ | $\frac{\text { Memory }}{}$ |
| :--- | :---: | :---: | :---: |
| Before Execution | 00000000 | 00000016 | 00000003 |
| After Execution | 00000002 | 00000001 | 00000003 |

## LOGICAL INSTRUCTIONS

## ETR EXTRACT

ETR performs a logical "AND" between corresponding bits of the A Register and the effective memory location and places the result in A . This instruction performs the operation bit by corresponding bit according to the following:

| A | $\underline{M}$ | Result in $A$ |
| :---: | :---: | :---: |
| 0 | 0 | 0 |
| 0 | 1 | 0 |
| 1 | 0 | 0 |
| 1 | 1 | 1 |

Registers Affected: A
Timing: 2

EXAMPLE :

|  | A | M |
| :--- | :---: | :---: |
| Before Execution | 64231567 | 00777600 |
| After Execution | 00231400 | 00777600 |

MRG MERGE

MRG performs a logical "Inclusive OR" between corresponding bits of the A Register and the effective memory location and places the result in A. This instruction performs the operation bit by corresponding bit, as follows:

| $\underline{A}$ | $\underline{M}$ | $\frac{\text { Result in } A}{}$ |
| :---: | :---: | :---: |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 1 |

Registers Affected: A
Timing: 2
EXAMPLE:

|  | A | $\underline{M}$ |
| :--- | :---: | :---: |
| Before Execution | 06446254 | 02340712 |
| After Execution | 06746756 | 02340712 |

EOR EXCLUSIVE OR

EOR performs a logical "Exclusive OR" between corresponding bits of the A Register and the effective memory location and places the result in A. This instruction performs the operation bit by corresponding bit, as follows:

| A | $M$ | Result in $A$ |
| :---: | :---: | :---: |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 0 |

Registers Affected: A
Timing: 2
EXAMPLE:

|  | A | M |
| :--- | :---: | :---: |
| Before Execution | 34165031 | 70077021 |
| After Execution | 44112010 | 70077021 |

The proper memory word configuration logically inverts selected bit positions of the A Register. If all "ones" appear in the memory word, a one's complement of $A$ results.

EXAMPLE :

|  | A | M |
| :--- | :---: | :---: |
| Before Execution | 10357211 | 77777777 |
| After Execution | 67420566 | 77777777 |

## REGISTER CHANGE INSTRUCTIONS

The facility to operate on and exchange data between the A, B, and Index Registers is available within the set of microinstructions in the Register Change Group.

All instructions in the group use the same operation code, 46. Bit positions 14 through 23 of the address field specify the function to be performed by each micro-instruction. The programmer may specify combinations of address bits to perform simultaneous operations.

If the selected bits copy two registers into a third during one operation, a merge of the former two registers into the latter results.

If the selected control bits copy into a register and clear that same register, the clear has no effect.

The function of each address bit is:
Instruction Bit Octal Position Octal Value Function

| 1 | OO | 2 | Clear X |
| :---: | :---: | :---: | :---: |
| 23 |  | 1 | Clear A |
| 22 | O7 | 2 | Clear B |
| 21 |  | 4 | Copy (A) into B |
| 20 |  | 1 | Copy (B) into A |
| 19 | O6 | 2 | Copy (B) into $X$ |
| 18 |  | 4 | Copy ( X ) into B |
| 17 |  | 1 | Bits 15-23 only* |
| 16 | O5 | 2 | Copy ( $X$ ) into $A$ |
| 15 |  | 4 | Copy ( $A$ ) into $X$ |
| 14 | O4 | 1 | Copy -(A) into A |

*See STORE EXPONENT (4600122) for special functions of this bit.

EXAMPLE:
The following instruction copies ( $A$ ) into $B$ and clears the A Register:

$$
04600005
$$

Both functions occur simultaneously, that is, within the one cycle time of the instruction.

Indirect addressing and indexing do not apply to these instructions.

These instructions require one machine cycle regardless of the number of functions performed. As an aid to the programmer, the most useful combinations have mnemonic designations assigned to them that are recognized by standard XDS programming systems.

CLA CLEARA

CLA clears the contents of the A Register to zero.
Registers Affected: A
Timing: 1

CLB
CLEAR B

CLB clears the contents of the $B$ Register to zero.
Registers Affected: B
Timing: 1

CLR CLEARAB

CLR clears the contents of both the $A$ and $B$ Registers to zero.
Registers Affected: A, B Timing: I

CAB COPY A INTO B

$C A B$ copies the contents of the $A$ Register into the $B$ Register.
Registers Affected: B
Timing: 1

CBA COPY B INTO A

CBA copies contents of the B Register into the A Register.
Registers Affected: A
Timing: 1

## XAB EXCHANGE A AND B

$X A B$ copies the contents of the A Register into the B Register and, simultaneously, copies the contents of the B Register into the A Register.

Registers Affected: A, B
Timing: 1

BAC copies the contents of the $B$ Register into the $A$ Register and, simultaneously, clears the $B$ Register to zero.

Registers Affected: A, B
Timing: 1
ABC COPY A INTO B, CLEAR A

$A B C$ copies the contents of the $A$ Register into the $B$ Register and, simultaneously, clears the A Register to zero.

Registers Affected: A, B
Timing: 1
CLX CLEAR INDEX REGISTER

The contents of the Index Register are set to zero.
Registers Affected: X Timing: 1

## CXA COPY INDEX INTO A

CXA copies the contents of the Index Register into the $A$ Register.

Registers Affected: A
Timing: 1
CAX COPY A INTO INDEX

CAX copies the contents of the A Register into the Index Register.

XXA copies the contents of the Index Register into the A Register and, simultaneously, copies the contents of the A Register into the Index Register.

CBX
COPY B INTO INDEX

CBX copies the contents of the B Register into the Index Register. Registers Affected: X

Timing: 1
CXB COPY INDEX INTO B

$C X B$ copies the contents of the Index Register into the B Register. Registers Affected: B

Timing: 1

XXB EXCHANGE INDEX AND B

$X X B$ copies the contents of the Index Register into the $B$ Register and, simultaneously, copies the contents of the B Register into the Index Register.

Registers Affected: B, X
Timing: 1

## STE STORE EXPONENT

STE copies the least significant nine bits of the B Register into the Index Register, extends bit 15 of the Index Register (the sign of the exponent) into bit 0 , and then clears the nine least significant bits of $B$.

EXAMPLE:

| Before Execution | 64152713 | --- |
| :--- | :---: | :---: |
| After Execution | 64152000 | 77777713 |

Note: This instruction assists in the manipulation of floating-point, double precision numbers, where the fraction is stored in the high order 39 bits and the exponent in the low order nine bits of the combined $A B$ Register. (See Floating-Point Operations, this section.)

Registers Affected: B, X
Timing: 1

LDE copies the least significant nine bits of the Index Register into the least significant nine bits of the B Register and clears the nine least significant bits of $B$ prior to the transfer.

## EXAMPLE:

|  | $\underline{B}$ | $\underline{\text { Index }}$ |
| :--- | :---: | :---: |
| Before Execution | 34765712 | 00000151 |
| After Execution | 34765151 | 00000151 |

Note: This instruction assists in the manipulation of floating-point, double-precision numbers, where the fraction is stored in the most significant 39 bits and the exponent in the least significant nine bits.

Registers Affected: B
Timing: 1

## XEE EXCHANGE EXPONENTS

| 0 | 46 |  | 00160 |
| :---: | :---: | :---: | :---: |
| 0 |  |  |  |

XEE exchanges the least significant nine bits of the B Register and the Index Register. The exchange loses no information. The new bit 15 of the Index Register (the sign of the exponent) then extends into bit 0 .

## EXAMPLE:

|  | $\underline{\text { B }}$ | $\underline{\text { Index }}$ |
| :--- | :---: | :---: |
| Before Execution | 67142355 | 77777133 |
| After Execution | 67142133 | 00000355 |

Note: This instruction assists in the manipulation of floating-point, double-precision numbers, where the fraction is stored in the most significant 39 bits and the exponent in the least significant nine bits.

Registers Affected: B, Ximing: 1

CNA COPY NEGATIVE INTO A

CNA copies the two's complement of the contents of the A Register into the A Register.

Registers Affected: A
Timing: 1

## BRANCH INSTRUCTIONS

Branch instructions conditionally or unconditionally change the course of the program by altering the contents of the program counter. The programmer should note that these instructions branch to locations determined by the effective address; this means that the branch can operate with all levels of indirect and indexed addressing.

## BRU BRANCH UNCONDITIONALLY

BRU takes the next instruction from the location determined by the effective address.

A BRU instruction with an Indirect Address bit equal to "one" clears the highest priority interrupt level then active in addition to branching to the effective location.

Registers Affected: P
Timing: 1

BRX INCREMENT INDEX AND BRANCH

BRX increments the contents of the entire Index Register by one. If the resultant Index Register value contains a " 1 " in bit position 9 of the index, the computer transfers control to the effective location. If not, it takes the next instruction in sequence.

If a BRX instruction is indexed, any transfer of control is to the effective address determined by the value of the index immediately prior to the execution of BRX. The test for transfer is on the incremented value of the Index Register, just as if the BRX instruction were not indexed.

The most significant bits of the Index Register (bits $0-8$ ) have no effect on the execution of the instruction, but may be affected by it.

If a branch occurs, an interrupt cannot occur following the execution of this instruction.

EXAMPLE:

| Location | Instruction |  | $\times$ Register |
| :---: | :---: | :---: | :---: |
| 0777 | STA | 1500 | 77777776 |
| 1000 | BRX | 1006 | 7777777 |
| $1001$ | LDA | $2000$ |  |
| 1006 | BRX | 1001 | 00000000 |
| 1007 | LDA | 2100 | 00000000 |

The execution of these instructions is in the following order as given by their locations:

$$
\begin{aligned}
& 0777 \\
& 1000 \\
& 1006 \\
& 1007
\end{aligned}
$$

Timing: 1, if branch
2, if no branch

BRM MARK PLACE AND BRANCH

BRM stores the contents of the Register (the address of the BRM instruction itself) in the effective memory location and transfers control to the effective memory location plus one. BRM also stores the status of the Overflow Indicator in bit 0 of the effective location and EM3 and EM2 in bits 3-5 and $6-8$, respectively. Bits 1, 2 and bit 9 are zero.

EXAMPLE:

| Location | Instruction | EM3 | EM2 |  |
| :---: | :---: | :---: | :---: | :---: |
| 01517 | BRM 522 | 3 | 2 |  |
|  |  | Overflow Indicator | Location 0522 | P <br> Register |
| Before Execution |  | 1 (on) | --- | 01517 |
| After Execution |  | 1 (on) | 43201517 | 00523 |

Note: Use this instruction to enter subroutines where a return to the main program is desired after the subroutine has been completed. Use RETURN BRANCH (51) to return to the main program.

Registers Affected: M
Timing: 2

BRR
RETURN BRANCH

BRR copies the contents of the effective memory location into an internal register and increments the contents by one. The instruction then stores the least significant 14 bits in the $P$ Register. It also performs a logical OR between bit 0 and the Overflow Indicator; and places the result in the Overflow Indicator. There is no change in the contents of the effective memory location.

EXAMPLE:

| Location | Contents |
| :---: | :---: |
| 2100 | BRR 2000 |
| 2000 | 00003220 |

If the computer executes the instruction in location 2100, it takes the next instruction from location 322 . Location 2000 still contains 00003220.

Note: Use BRR to return to the main program after completion of a subroutine in conjunction with MARK PLACE AND BRANCH (43).
The Memory Extension registers are unaffected by BRR.
Registers Affected: Overflow Indicator Timing: 2

## TEST AND SKIP INSTRUCTIONS

SKE SKIP IF A EQUALS MEMORY

SKE compares the contents of the A Register with the contents of the effective memory location. If the contents of $A$ equal the contents of the effective location, the computer skips the next instruction in sequence and executes the following instruction. If the contents of $A$ do not equal the contents of the effective location, the computer executes the next instruction in sequence. SKE alters neither A nor memory.

Registers Affected: None Timing: | 2, if no skip |
| :--- |
| 3, if skip |

SKG SKIP IF A GREATER THAN MEMORY

SKG algebraically compares the contents of the A Register with the contents of the effective memory location. If the contents of $A$ are greater than the contents of the effective location, the computer skips the next instruction in sequence and executes the following instruction. If the contents of $A$ are less than or equal to the contents of the effective location, the computer executes the next instruction in sequence. SKG alters neither A nor memory.

Registers Affected: None
Timing: 2, if no skip 3, if skip

## SKM SKIP IF A EQUALS MEMORY ON B MASK

SKM compares selected bits of the contents of the A Register with the corresponding bits in the contents of the effective memory location. If the selected bits in $A$ are identical to the selected bits in the contents of the effective memory location, the computer skips the next instruction in sequence and executes the following instruction. If the selected bits in the contents of the A Register are not identical to the contents of the effective location, the computer executes the next instruction in sequence.

The programmer selects the bits in A to be compared by placing ones in the corresponding bit positions of the $B$ Register and zeros in the remaining bit positions of $B$.

SKM considers the contents of $A, B$, and the effective location to be unsigned, 24-bit, non-numeric quantities, and does not alter them.

EXAMPLE :

| A | B | $\frac{\text { Memory }}{57643240}$ |
| :---: | :---: | :---: |

Since SKM compares bit positions 8-14 only (as determined by $B$ ), and $(A)=(M)$ in these positions, a skip occurs. Note that if $(B)=0$, a skip occurs regardless of $(A)$ and $(M)$. Note also that if $(B)=7777777$, instruction SKM functions identically like instruction SKE.

Registers Affected: None

$$
\begin{gathered}
\text { Timing: } \begin{array}{c}
2, \text { if no skip } \\
3, \text { if skip }
\end{array}
\end{gathered}
$$

## SKA SKIP IF A AND MEMORY DO NOT COMPARE ONES

SKA compares the contents of the A Register, bit by bit, with the contents of the effective memory location. If the contents of the A Register and the contents of the effective location do not have any one pair of ones in corresponding bit positions, the computer skips the next instruction in sequence and executes the following instruction. If the contents of the A Register and the contents of the effective location do have at least one pair of l-bits in corresponding bit positions, the computer executes the next instruction in sequence.
The instruction logically ANDS corresponding bits in A and Memory, based on the following table :

| $\frac{A}{0}$ | $\frac{\text { Memory }}{0}$ | Result |
| :---: | :---: | :---: |
| 0 | 1 | 0 |
| 0 | 0 | 0 |
| 1 | 1 | 0 |
| 1 | 1 |  |

If the result produces a "l" in any bit position, a skip does not occur.

Note: Different configurations of the memory word result in a wide variety of conditional instructions for use by the programmer. Some representative configurations are:

| Memory Configuration | Instruction |
| :---: | :---: |
| 40000000 | Skip if $A$ is Positive |
| 7777777 | Skip if $A=0$ |
| 00000001 | Skip if $A$ is Even |
| Contents of A Register |  |
| 40000000 | Skip if Memory is Positive |
| 77777777 | Skip if Memory $=0$ |
| 00000001 | Skip if Memory is Even |

Registers Affected: None
Timing: 2, if no skip 3, if skip

This instruction functions identically like SKA but operates on the B Register.

$$
\begin{array}{ll}
\text { Registers Affected: None } \quad \text { Timing: } \begin{array}{l}
2, \text { if no skip } \\
3, \text { if skip }
\end{array}
\end{array}
$$

SKN SKIP IF MEMORY NEGATIVE

If the contents of the effective memory location are negative, i.e., if $\left(M_{0}\right)=1$, the computer skips the next instruction in sequence and executes the following instruction. If the contents of the effective location are positive or zero, the computer executes the next instruction in sequence.

Registers Affected: None Timing: 2, if no skip 3, if skip

SKR REDUCE MEMORY, SKIP IF NEGATIVE

SKR reduces the contents of the effective memory location by one, places the result in the same location, and then tests for negative. If the contents of the effective memory location are then negative, the computer skips the next instruction in sequence and executes the following instruction. If the contents of the effective location are positive or zero, the computer executes the next instruction in sequence.

An overflow occurs if the initial contents of memory are 40000000 . The result in memory in this case is 37777777.
Registers Affected: M, Overflow Indicator Timing: 3
SKD DIFFERENCE EXPONENTS AND SKIP

SKD subtracts the contents of bits 15 through 23 of the effective memory location from bits 15 through 23 of the B Register. It then stores the absolute magnitude of the difference in bits 15 through 23 of the $X$ Register and destroys the contents of bits 0 through 14 of the $X$ Register. If the 9 -bit contents of the effective location are less than or equal to the 9-bit contents of the $B$ Register, the computer executes the next instruction in sequence. If not, the computer skips the next instruction in sequence and executes the following instruction.

Registers Affected: X
Timing: 2, if no skip 3, if skip

## SHIF INSTRUCTIONS

The shift instructions operate on the contents of the $A$ and $B$ Registers and offer a complete facility for right and left shifting, cycling, and normalizing the contents of these two registers. The $A$ and $B$ Registers, in combination, form a doublelength register whose double-length contents can be shifted, cycled, or normalized. This double-length register is named "AB."

When the contents of the $A B$ Register shift right, bits from bit position 23 of the $A$ Register shift into bit position 0 of the $B$ Register. When the $A B$ Register shifts left, bits from bit position 0 of the $B$ Register shift into bit position 23 of the $A$ Register.

The 48-bit contents of the $A B$ Register may be cycled using the shift instructions. When the contents of the $A B$ Register cycle, the bits that shift from one end of the one register copy into the other end of the other register.

These instructions use the instruction code to determine the direction of shift ( $66=$ right; $67=$ left); bits $10-11$ (octal position 3 ) of the instruction address determine the method of shifting as follows:

$$
\text { Bits } 10,11
$$

Octal Value

0
2
1

Function
AB Shift
AB Cycle
Normalize (Left only)

AB Shift

Normalize (Left only)

Indirect addressing is permissible with these instructions, bits 10 and 11 of the effective address determining the method of shifting.

Since the type of shift and number of shifts are determined by bits 10 through 23 of the effective address, indirect addressing and/or indexing drastically alter the action specified in a shift instruction. When procuring the effective location for a shift instruction,

14-bit indexing is performed with all indirectly addressed operands, and
9-bit indexing is performed with all directly addressed operands.

That is, indexing with a direct address can affect only the 9bit shift count.

When the computer interprets a shift instruction, bit positions 15 through 23 of the effective address of the instruction determine the amount of the shift. The computer treats these nine bits as an unsigned count. If the initial count is equal to zero, no shifting occurs. If the initial count is greater than 48, it is set to 48 prior to shifting. Once the shift begins, the count reduces by one for each position shifted until it reaches zero. The count $C$ in the following instructions indicates the number of places to be shifted. Shift timing is:

| Left Shift and <br> Normalize Count | Cycles |
| :---: | :---: | :---: |$\quad$| Right Shift <br> Count |  |  |
| :---: | :---: | :---: |
|  | 2 | $0-3$ |
| $0-6$ | 3 | $4-14$ |
| $7-26$ | 4 | $15-25$ |
| $27-46$ | 5 | $26-36$ |
| $47-48$ | 6 | $37-47$ |
|  | 7 | 48 |

RSH
RIGHT SHIFT AB

RSH shifts the contents of the $A B$ Register (that is, $A$ and $B$ Registers) right the number of places specified in bits 15 through 23 of the effective address. The bit in the sign position of $A$ does not shift, but its value copies into the vacated bit positions of the shifted number. The bit in the sign position of $B$ shifts. Bits shifted out of $A_{23}$ shift into $B_{0}$. Bits shifting past position $B_{23}$ are lost.

Registers Affected: A, B
Timing: 2-7

## EXAMPLE:

The instruction is: RSH 00022

|  | A | B |
| :--- | :---: | :---: |
| Before Execution | 45261237 | 27651260 |
| After Execution | 77777745 | 26123727 |

Note: This instruction may perform scaling of floating-point numbers by use of indexing, where the difference of exponents is in the Index Register as positive quantity.

LRSH LOGICAL RIGHT SHIFT AB

| 0 | $\times$ | 0 | 66 | 0 | 24 | $C$ | $C$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 2 | 3 |  | 8 | 9 | 10 | 1415 |

LRSH performs a logical right shift. It shifts the contents of $A B$ right the number of places specified in bits 15 through 23 of the effective address. The bits in the sign position of $A$ and the sign position of $B$ shift with the rest of the number. Vacated bits on the left fill with zeros. Bits shift out of $A_{23}$ into $B_{0}$. Bits shifting past $\mathrm{B}_{23}$ are lost.

Registers Affected: A, B
Timing: 2-7
RCY RIGHTCYCLE AB

RCY shifts the contents of the $A B$ Register right the number of places specified in bits 15 through 23 of the effective address. The bit in the sign position of $B$ shifts like any other bit in $B$.
Bits shifting out of $A_{23}$ shift into $B_{0}$. Bits from bit position 23
of $B$ go into bit position 0 of $A$. The computer treats the doublelength register as if it were circular and cycles it onto itself; it loses no bits.

```
Registers Affected: A, B Timing: 2-7
```

## EXAMPLE:

The instruction is: RCY 00017

|  | A | B |
| :--- | :---: | :---: |
| Before Execution | 61235703 | 41537701 |
| After Execution | 37701612 | 35703415 |

## LSH LEFT SHIFT AB

LSH shifts the contents of the $A B$ Register left the number of places specified in bits 15 through 23 of the effective address. Bits shift left through the sign position of $A$, but when a bit, different in value from the original sign, shifts into the sign position, the computer sets the Overflow Indicator. Bits shifting out of $B_{0}$ go into $A_{23}$. Bits shifting past position 0 in $A$ are lost. Zeros fill the vacated bit positions on the right end of the B Register.

Registers Affected: A, B, Overflow Indicator Timing: 2-5
EXAMPLE:
The instruction is: LSH 00022

|  | $\underline{A}$ | $\underline{B}$ |
| :--- | :---: | :---: |
| Before Execution | 46712370 | 64132711 |
| After Execution | 70641327 | 11000000 |

LCY
LEFT CYCLE AB

LCY shifts the contents of the AB Register left the number of places specified in bits 15 through 23 of the effective address. The bits in the sign positions of $A$ and $B$ shift like any other bits in the number. Bits shifting out of $B_{0}$ shift into $A_{23}$. The instruction copies bits that shift from bit position 0 of $A$ into bit position 23 of B . The computer treats the double-length register as if it were circular and cycles it onto itself. It loses no bits.

Registers Affected: A, B
Timing: 2-5

## EXAMPLE:

| The instruction is: LCY 00011 | A | B |
| :---: | :---: | :---: |
| Before Execution | 71432560 | 34156723 |
| After Execution | 32560341 | 56723714 |

NOD

NOD shifts the contents of the $A B$ Register left until (1) a bit appears in position 1 of $A$ that is not equal to the bit in the sign position of $A$, or (2) until $C$ shifts occur. The computer keeps count of the number of places shifted and when the normalize operation is completed, it subtracts the count from the contents of the Index Register and places the result back into the Index. If, in the attempt to normalize, shifting exceeds 48 places, the contents of the $A B$ Register were initially zero. In this case, the computer subtracts 48 from the Index Register. Zeros fill the vacated positions.

The number, C, placed in address bit positions 15 through 23, is an upper limit for the number of left shifts that will occur. The programmer must ensure that $C$ is sufficiently large to permit a complete normalization.

EXAMPLE:
NOD 30

|  | $\underline{A}$ | $\underline{B}$ | $\underline{X}$ |
| :---: | :---: | :---: | :---: |
| Before Execution | 00004632 | 76124035 | 00000000 |
| After Execution | 23153705 | 20164000 | 77777765 |
| Registers Affected: A, B,X |  | Timing: 2-5 |  |

REO RECORD EXPONENT OVERFLOW

This instruction causes the Overflow Indicator to be turned on if the content of bit 14 of the Index Register is not equal to the content of bit 15 of the Index Register.

This instruction is normally used after a normalize operation to record a floating-point exponent overflow. See Floating-Point Operations, this section.

Registers Affected: Overflow Timing: 1

## CONTROL INSTRUCTIONS

## HLT HALT

When the computer executes this instruction, it halts computation and lights the HALT indicator in the console. Before halting, the computer increments the P Register and brings the next
instruction to the C Register to be displayed. To resume computation, the operator must first set the RUN-IDLE-STEP switch to IDLE, then back to RUN.

The computer then executes the next instruction, according to the P Register, and turns the HALT light off when the switch is set to either the RUN or STEP position.

Indirect addressing and indexing do not apply to this instruction.
When the computer executes HLT, all internal computation ceases at the end of the present instruction being executed. If an input/output operation is in progress, it continues until completed. Computation automatically resumes with the occurrence of a program interrupt, if the RUN-IDLE-STEP switch is still in the RUN position and the interrupt system is enabled.

Registers Affected: None
Timing: $1+$ wait

NOP NO OPERATION

|  | 0 | 20 |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 123 |  | 89 |  |  |  |

Executing NOP does not affect the A Register, B Register, $X$ Register, or memory. Indirect addressing and indexing do not apply to this instruction.

Registers Affected: None
Timing: 1

EXU EXECUTE

EXU causes the contents of the effective memory location to be executed as an instruction without altering the contents of the Program Counter. If the effective location is not a Branch, Skip, or another Execute instruction, the computer executes the next instruction in sequence following the Execute instruction, after it executes the contents of the effective location.

If the contents of the effective memory location are a Branch instruction, program control goes to the effective address of the branch and not to the next instruction in sequence following the Execute instruction.

If the contents of the effective memory location are a skip instruction, then, depending on the skip decision, program control returns to the next instruction, or the next instruction plus one, following the Execute instruction.

If the contents of the effective memory location are another Execute instruction, the above process continues identically, with the normal return being the initial Execution location plus one. This process can cascade indefinitely.

Registers Affected: None
Timing: 1

## BREAKPOINT TESTS

This instruction tests the status of the Breakpoint switches singly or in any combination. If any one of the Breakpoint switches tested is reset, the computer skips the next location in sequence and executes the following instruction. If none of the Breakpoint switches tested is reset, the computer executes the next instruction in sequence.

| Mnemonic | Name of Instruction | Octal Configurat |
| :---: | :---: | :---: |
| BPT 1 | Breakpoint No. 1 Test | 04020400 |
| BPT 2 | Breakpoint No. 2 Test | 04020200 |
| BPT 3 | Breakpoint No. 3 Test | 04020100 |
| BPT 4 | Breakpoint No. 4 Test | 04020040 |

Registers Affected: None
Timing: 1, if no skip 2, if skip

## OVERFLOW INSTRUCTIONS

OVt OVERFLOW INDICATOR TEST AND RESET

This instruction tests the status of the Overflow Indicator, skips or not accordingly, and turns the indicator off. If the indicator is off, the computer skips the next instruction in sequence and executes the following instruction. If the indicator is on, the computer executes the next instruction in sequence.

ROV unconditionally resets the Overflow Indicator (clears to zero).

Registers Affected: Overflow
Timing: 1

## MEMORY EXTENSION INSTRUCTIONS

SET EXTENSION REGISTER
006 200SR

| 0 | 06 | 2 |  | S | R3 | R2 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 |  |  |  | 17 |  | 21 | 23 |

This instruction sets (or loads) Memory Extension Register 3 and/ or 2 with the contents of fields R3 and R2, respectively.
If S3, position 16, is a 1 , the computer sets the contents of R3, bit positions 18 through 20, into EM3. This destroys the previous contents of EM3. If S3 is a 0, SET does not affect EM3.
If S2, position 17, is a 1, the computer sets the contents of R2, bit positions 21 through 23, into EM2. This destroys the previous contents of EM2. If S2 is a $0, S E T$ does not affect EM2.
If both S3 and S2 are 1, SET loads both EM3 and EM2 simultaneously. If both S 3 and S 2 are 0 , SET is effectively a "no-op" instruction.
Registers Affected: EM3, EM2
Timing:

## EXTENSION REGISTER TEST

$0404000 T$

This instruction tests the contents of the extension register as follows:

## I TEST

0 No test. The computer executes the next instruction in sequence.

1 Test EM3. If $(E M 3) \neq 3$, the computer skips the next instruction in sequence. If (EM3) $=3$, the computer executes the next instruction in sequence.

2 Test EM2. If (EM2) $\neq 2$, the computer skips the next instruction in sequence. If (EM2) $=2$, the computer executes the next instruction in sequence.

3 Test EM3 and EM2. If (EM3) $\neq 3$ or $(E M 2) \neq 2$, the computer skips the next instruction in sequence. When $(E M 3)=3$ and $(E M 2)=2$, the computer executes the next instruction in sequence.

Registers Affected: None
Timing: 1, if no skip 2, if skip

## FLOATING POINT OPERATIONS

Floating-point operations are performed via Programmed Operator subroutines in either single or double precision. Double precision is used when accuracy of approximately 11 decimal digits must be maintained. Single precision permits faster execution times with approximately seven decimal digits of accuracy.

These standard Programmed Operators assume that the most significant word is in $A$, or stored in location $M+1$, while the less significant word is in $B$, or memory location $M$. See Section I, Floating-Point Format.

## DOUBLE PRECISION FLOATING-POINT OPERATIONS

Double precision floating-point operations are performed using a fractional number of 39 bits ( 38 bits plus sign) and an exponent of nine bits (eight bits plus sign). Numbers are represented with a fraction equal to 11 decimal digits plus sign and a multiplier as high as $10^{ \pm 77}$.

The Programmed Operator subroutines that perform double precision, floating-point operations are:

| Designation | Name | Function | Approx. Execution Time |
| :---: | :---: | :---: | :---: |
| FLA | Floating Add | $\begin{aligned} & \text { Floating }(A, B) \\ & +(M+1, M) \rightarrow A, B \end{aligned}$ | $92 \mu \mathrm{sec}$ |
| FLS | Floating Subtract | Floating ( $\mathrm{A}, \mathrm{B}$ ) <br> - $(M+1, M) \rightarrow A, B$ | $101 \mu \mathrm{sec}$ |
| FLM | Floating Multiply | Floating ( $A, B$ ) $x(M+1, M) \rightarrow A, B$ | $147 \mu \mathrm{sec}$ |
| FLD | Floating Divide | $\begin{aligned} & \text { Floating }(A, B) \\ & \div(M+1, M) \rightarrow A, B \end{aligned}$ | $157 \mu \mathrm{sec}$ |

## SINGLE PRECISION, FLOATING-POINT OPERATIONS

Single precision, floating-point operations are performed using a fractional number of 24 bits ( 23 bits plus sign) and an exponent of nine bits (eight bits plus sign). Numbers are represented with a fraction equal to six decimal digits plus sign and an exponent as high as $10^{ \pm 77}$.

The Programmed Operator subroutines that perform single precision floating-point operations are:

| Designation | Name | Function | Approx. Execution Time |
| :---: | :---: | :---: | :---: |
| FSA | Floating Add, Single Precision | Floating $(A)+(M+1) \rightarrow A$ Exponent in $B, M$ | $77 \mu \mathrm{sec}$ |
| FSS | Floating Subtract, Single Precision | $\begin{aligned} & \text { Floating }(A)-(M+1) \rightarrow A \\ & \text { Exponent in } B, M \end{aligned}$ | $80 \mu \mathrm{sec}$ |
| FSM | Floating Multiply, Single Precision | Floating $(A) \times(M+1) \rightarrow A$ Exponent in $B, M$ | $54 \mu \mathrm{sec}$ |
| FSD | Floating Divide, Single Precision | Floating $(A) \div(M+1) \rightarrow A$ Exponent in $B, M$ | $101 \mu \mathrm{sec}$ |

## XDS 930 INSTRUCTIONS FOR <br> FLOATING-POINT OPERATIONS

To maintain accuracy in floating-point operations, all fractional numbers must be in normalized form, that is, shifted to the left to eliminate leading insignificant digits. When a floating-point arithmetic operation has been performed, the fractional number must be normalized and the exponent adjusted to reflect the change in the fractional number. NORMALIZE AND DECREMENT $X$ is used to:
(a) shift the fractional number to the left to eliminate leading insignificant digits.
(b) adjust the exponent (contained in the $X$ Register) for each bit position shifted.

To determine whether the adjusted exponent has overflowed the 15th bit in the Index Register during the above normalize operation, the instruction, RECORD EXPONENT OVERFLOW (REO), is used. This instruction causes the Overflow Indicator to be turned on if $\left(\mathrm{X}_{14}\right) \neq\left(\mathrm{X}_{15}\right)$.
When performing floating-point addition and.subtraction, it is necessary to align the numbers so that the exponents are equal before the arithmetic is performed. The single instruction, DIFFERENCE EXPONENTS AND SKIP (74):
(a) determines which of the numbers is to be shifted, and
(b) determines the number of positions to be shifted to align the numbers. Alignment is performed using SHIF T AB, Index bit equal to one, with the number of shifts located in the $X$ Register.

Manipulation of the exponent is required in all floating-point operations. Capability is included in the Register Change instruction to:
(a) transfer the exponent portion of the word to and from the $A, B$, and $X$ Registers, and
(b) clear exponent bits when arithmetic is to be performed.

These operations can be performed in effective combinations in one machine cycle.

## III. INTERRUPT SYSTEM

## PRIORITY INTERRUPT SYSTEM

XDS 900 Series Computers contain a priority interrupt system that provides added program control of input/output operations, aids in programming simultaneous input/output and compute operations, and allows immediate recognition of special external conditions.

Interrupts, as specified by the program, can signal when a single word or a block of words has been transmitted. When received, the internal logic examines the interrupt signal and causes the computer to interrupt the program sequence at the end of the execution cycle of the current instruction. Without disturbing the Program Counter Register, the computer transfers program control to one of a selected set of memory locations. A MARK PLACE AND BRANCH (BRM) instruction in this location saves the contents of the program counter, EM3, EM2, and overflow indicator and transfers to the particular interrupt servicing routine required. Entrance to the proper service routine occurs since each interrupt has a unique interrupt location. To exit from the routine, a BRANCH UNCONDITIONALLY (BRU) instruction using indirect addressing returns control to the next instruction in proper sequence in the main program; it also clears the interrupt. Note that when an interrupt occurs causing the execution of the BRM in the interrupt level, the address stored in the mark location is the location plus one of the instruction that was interrupted. In other words, the computer increments the program counter prior to inspecting its registers for an interrupt condition.

The priority interrupt system has up to 896 System interrupt levels. The levels are numbered upward from 200 and have priority according to number; the higher priority levels have a smaller number. See Table 3-1, Interrupt Locations, for the specific assignment.

The two standard as well as the additional interrupts obtained with XDS optional hardware are located at interrupt levels numbered from 30. In general, these have priority according to number like the System interrupts. Note that interrupts 30-77 have priority over any System interrupt (200 or more). The Power Fail-Safe option interrupts (in locations 36 and 37) are "out-of-order" interrupts; they have the highest priority of all.

When an interrupt has occurred and its service subroutine has been entered, an interrupt of higher priority can interrupt the subroutine and gain program control for the servicing of its more important operation. But an interrupt of lower priority cannot interrupt an interrupt-processing subroutine of a higher level. Thus, the priority interrupt system allows interrupts to be arranged according to their importance and/or according to their need for speedy servicing.

The above type of interrupt is called a normal priority interrupt to differentiate from another interrupt feature, the single-
instruction interrupt. This different kind of interrupt causes the execution of only one instruction before automatically clearing itself and returning to the program that it interrupted. For example, if an external clock source is connected to the computer so that it pulses an interrupt line at set intervals, the program can maintain a programmed real-time clock. Each time the external pulse causes an interrupt, the program executes the single instruction, MEMORY INCREMENT (MIN), to add one to the memory word selected for use as the programmed real-time clock. The main program can examine this memory location whenever necessary to determine how many time increments have elapsed since the clock was started.

If the single instruction that is executed is a branch instruction, and the branch occurs, the interrupt is cleared but there is no return to the program that was interrupted. This type of interrupt needs no branch instruction to clear it.

Since the single-instruction interrupt performs just one instruction and clears itself, it can be sandwiched into a priority system without disturbance. Any of the optional System interrupts (200-1777) can be single- or normal-instruction interrupts in any combination desired.

## PRIORITY INTERRUPT OPERATIONS

A normal priority interrupt level has three operational states: Inactive, Waiting, and Active.

In the inactive state, no interrupt signal has been received into the level and none is currently being processed by its interrupt servicing subroutine.

In the waiting state, an interrupt has been received into the level, but is not being processed. This situation may be due to an interrupt of higher priority being processed at this time. When all higher waiting interrupts have been processed, this level goes to the active state.

In the active state, the interrupt has caused the main program to recognize its presence and has transferred to its assigned interrupt location where it is being processed. When the interrupł processing is completed, a BRANCH UNCONDITIONALLY (BRU) instruction with indirect addressing exits from the service subroutine by transferring control to the proper return location. This branch instruction also sets the interrupt level to the inactive state.

A single-instruction interrupt operates in the same way as the normal priority interrupt in the inactive and waiting states. However, when acknowledged, this interrupt enters the active state, and remains there during the execution of one instruction. At the completion of the one instruction, the singleinstruction interrupt returns to the inactive state without the aid of a branch instruction. The single instruction must have a two-cycle or greater execution time.

## NTERRUPT CONTROL

Two program control features are available in the interrupt system. These features are Arm/Disarm and Enable/Disable. Arm/Disarm controls whether an interrupt can proceed from the inactive state to the waiting state. When armed, an interrupt signal sets the interrupt to the waiting state. the disarmed condition causes that level to retain no record of an interrupt signal entering the level.

Enable/Disable operates on the entire interrupt system. When the interrupt system is enabled, the System interrupts (2001777) are enabled; when the interrupt system is disabled, the system interrupts are disabled. Enable/Disable operates differently for the interrupts obtained with XDS options (30-77). Enable/Disable has no effect on the Power Fail-Safe interrupts; they are always enabled and armed. See the last two subsections of this section for a description of how the channel interrupts are affected.
The control of the optional Arm/Disarm feature operates on individual System interrupt levels, that is, any chosen interrupt
level may be selectively armed or disarmed. But the instruction structure for Arm/Disarm allows operation on these interrupts in groups of sixteen.

## NON-INTERRUPTABLE INSTRUCTIONS

Three instructions prohibit interrupts following their execution. If a branch occurs, an interrupt cannot occur between the execution of INCREMENT INDEX AND BRANCH (BRX) and the instruction to which BRX branches. An interrupt cannot occur between the execution of ENERGIZE OUTPUT $M$ (EOM) and the instruction following it or between the execution of ENERGIZE OUTPUT TO DIRECT ACCESS CHANNEL (EOD) and the instruction following it.

## ENABLE/DISABLE INTERRUPT INSTRUCTIONS

Three instructions are available for setting, resetting, and testing the state of the INTERRUPT ENABLED indicator.

Table 3-1. Interrupt Location Assignments

| 30 | Channel Y | Count Equals Zero (End-of-Word) |
| :---: | :---: | :---: |
| 31 | Channel W | Count Equals Zero (End-of-Word) |
| 32 | Channel Y | End-of-Record (End-of-Transmission) |
| 33 | Channel W | End-of-Record (End-of-Transmission) |
| 36 | Power ON | Power Fail-safe interrupt: Power Return |
| 37 | Power OFF | Power Fail-safe interrupt: Power below safe limit |
| 56 | CPU Parity | During an instruction or operand fetch |
| 57 | 1/O Parity | During an IO operation under channel control |
| 60 | Channel C | Count Equals Zero (End-of-Word) |
| 61 | Channel C | End-of-Record (End-of-Transmission) |
| 62 | Channel D | Count Equals Zero (End-of-Word) |
| 63 | Channel D | End-of-Record (End-of-Transmission) |
| 64 | Channel E | Count Equals Zero |
| 65 | Channel E | End-of-Record |
| 66 | Channel F | Count Equals Zero |
| 67 | Channel F | End-of-Record |
| 70 | Channel G | Count Equals Zero |
| 71 | Channel G | End-of-Record |
| 72 | Channel H | Count Equals Zero |
| 73 | Channel H | End-of-Record |
| $\begin{aligned} & 74 \\ & 75 \end{aligned}$ | Clock Sync.) Clock Pulse | Locations 74, 75 are for the real-time clock |
| $\left.\begin{array}{l} 200 \\ 217 \end{array}\right\}$ | Group 0 Optional General-Purpose Interrupts |  |
| $\left.\begin{array}{l} 220 \\ 237 \end{array}\right\}$ | Group 1 Optional General-Purpose Interrupts |  |
| : | etc. |  |

EIR ENABLE INTERRUPT

EIR unconditionally sets the INTERRUPT ENABLED indicator and enables the interrupt system. If any interrupt levels are waiting, the one with the highest priority becomes active.

Registers Affected: None Timing: 1

DIR DISABLE INTERRUPT

DIR unconditionally resets the INTERRUPT ENABLED indicator and disables the interrupt system. This instruction does not change the current state of any interrupt level.

If the priority interrupt system is enabled, the computer skips the next instruction in sequence and executes the following instruction. If the priority interrupt system is disabled, the computer executes the next instruction in sequence.

If the priority system is disabled, the computer skips the next instruction in sequence and executes the following instruction. If the priority interrupt is enabled, the computer executes the next instruction in sequence.

Registers Affected: None

> Timing: 1, if no skip 2, if skip

## ARMING FEATURE (Optional)

The arming feature is controlled for a group of 16 interrupts by a word sent to the group with the ARM INTERRUPTS (AIR) instruction followed by the PARALLEL OUTPUT (POT) instruction. AIR operates only on System interrupts (200-1777).

## AIR ARM INTERRUPTS

AIR prepares the arm interrupt control unit to receive a control word for a group of 16 interrupt levels. A PARALLEL OUTPUT (POT) must always follow AIR, or an unpredictable operation results.

Registers Affected: None
Timing: 1

Section IV, Input/Output System, contains a discussion of PARALLEL OUTPUT (POT). The word that the POT instruction addresses has the following format:

The address field in bit positions 0 through 5 identifies which group of 16 interrupts in the system is being addressed. Address 00 refers to the group of locations 200-217. The C field controls what is done to the particular interrupt levels selected in bit positions 8 through 23. Bit position 8 refers to the lowestnumbered level of the group, therefore the one with highest priority. Bit position 23 refers to the last or highest-numbered level, the one with lowest priority. For example, a word of 00240000 arms level number 201.

The control operations are:

| Bit <br> Position <br> $6-7$ | Octal Octal <br> Position <br> Value | Not used |
| :--- | :--- | :--- |
| 00 | 0 | Arm all interrupt levels that are <br> selected by a 1 in bit positions <br> $8-23$ |
| 01 | 4 | Disarm all interrupt levels that are <br> selected by a 0 in bit positions <br> $8-23$ |
| 10 | 6 | Arm all interrupts selected by a 1 <br> and disarm all interrupts selected <br> by a 0 in bit positions $8-23$. |

## CHANNEL IWTERRUPT DESIGNATIONS

As shown in the Interrupt Location Table, each I/O channel has two interrupt levels. These reflect the two distinct uses of interrupts during channel input and output. Also, each W, Y, $C$, and D channel level has two names that reflect their use in the Extended or Compatible I/O Modes (see Section IV, Compatible/ Extended Input/Output Modes.

## END-OF-WORD/END-OF-TRANSMISSION INTERRUPT OPERATIONS; COMPATIBLE MODE

A program can use Channels $W$ and $Y$ as single-word, direct, program-controlled, input/output buffers. Special I/O instructions applicable to Channels $W$ and $Y$ control this type of operation (see Section IV). In this mode, the program can specify that interrupts occur as each word is transferred from the buffer to the peripheral device on output, or as soon as the buffer is filled from the peripheral device on input. This is the End-of-Word interrupt. The program can specify that an End-of-Transmission interrupt occurs when the buffer detects a signal such as End-of-Record from magnetic tape. During both input and output operations, this interrupt occurs when the peripheral device used in the transmission disconnects and the buffer becomes ready for another input/output operation.

These two interrupts also can control input/output termination for any communication channel when the program is operating the buffers in the block transmission or "interlaced" compatible mode (optional system). The End-of-Transmission interrupt operates in the fashion described above. In this mode, the End-of-Word interrupt onl y occurs on input. The End-of-Word interrupt occurs after the channel has read the number of words specified and then another word fills the buffer. If the program encounters the last word before an End-of-Transmission interrupt, the End-of-Word interrupt occurs after the next word is read. If an End-of-Record condition occurs first, the End-of-Transmission interrupt occurs. No End-of-Word interrupt occurs during output.

The Enable or Disable instructions "enable and arm" or "disable and disarm" the End-of-Word and End-of-Transmission interrupts when the channel is not operating in the extended interlace mode. When the EIR instruction is executed, the interrupt system is enabled and these interrupts are also armed; when DIR is executed, the system is disabled and these interrupts are also disarmed.

## COUNT EQUALS ZERO/END-OF-RECORD; EXTENDED MODE

When the XDS 930 Input/Output System uses channels within its full capabilities, XDS 930 input/output functions control interlaced block transmission operations (see Input/Output Functions, Section IV). The interrupts used with the extended input/output function control are Count Equals Zero and End-of-Record. The Count Equals Zero interrupt occurs when the last of the number of words specified is placed into or brought
from memory. The End-of-Record interrupt occurs when the channel receives an End-of-Record signal (gap). Input/output functions can alter this latter occurrence for use with magnetic tapes.

## EFFECTS OF THE ENABLE/DISABLE FEATURE ON ARMABLE INTERRUPTS

When operating an Input/Output Channel in the extended mode the interrupt Enable feature controls the Armable interrupts (Count Equals Zero and End-of-Record). If a channel generates an extended mode $1 / O$ interrupt while the system is disabled, the designated interrupt level goes to the Waiting state. When the program again enables the interrupt system, the interrupt goes to the Active state when its priority allows.

This feature allows the programmer great ease in handling multiple channel operations. The interrupt processing subroutine for one channel can disable the interrupt system while it processes the interrupt. During this time, the system receives all other interrupts in their respective levels and goes to the Waiting state until the system is again enabled.

Figure 3-1. Interrupt Arm-Enable Response

# IV. INPUT/OUTPUT INSTRUCTIONS 

## INTRODUCTION

The XDS 930 has a flexible, input/output system to complement its high, internal processing speed and versatile instructions. This system can transmit data in word, character, or single-bit form to and from the computer at the speed of internal computation. The input/outputsystem assumes control of conditions imposed by different characteristics of a wide variety of devices, but leaves a high degree of input/output control to the programmer.

This system includes the following types of input/output:
Buffered input/output of data words, each under direct program control
Communication channel input/output of characters or words, time-shared with memory and multiplexed with computation.
Communication channel input/output of characters or words, fully buffered and simultaneous with computation.
Direct parallel input/output of up to 24 bits of information to and from external equipment, completely controlled and sequenced externally.
Direct parallel input/output of up to 24-bit words to and from external static registers under program control.

Single-bit input/output, such as equipment on/off status, sense switches, and pulsing and sensing of special devices.

## DATA FLOW PATHS

The XDS 930 includes as standard equipment one Time-Multiplexed Communication Channel (TMCC), without interlacing capability, as well as provision for three additional channels. The interlace unit is available as an option. The $W$ and $Y$ channels are available with or without interlace; the C and D channels are available only with interlace. These channels are capable of automatically controlling the flow of data to and from memory at rates up to one word every 3.5 microseconds. These channels run independently of the central processor and only communicate with it to transfer data to or from memory.

In addition to the Time-Multiplexed Channels, a Direct Memory Access System is available. This system uses a path to memory separate from those used by the central processor. Up to four Direct Access Communication Channels (with direct access memory connections) can be attached to the Direct Access System. These channel operate like the time-multiplexed Channels except that they are faster and provide for a true overlap of input/output with processing.

A Data Multiplex System, which uses the direct access memory connection, is also available as an option. This system consists of a Data Multiplex Channel that accepts/transmits data words and memory addresses from many external devicesor subchannels, all of which may be in operation at the same time. The system is capable of transmitting up to 572,000 words per second simultaneous with computation (see Appendix A-11).

## COMMUNICATION CHANNELS

Using Channels W and Y , characters and words can be transmitted between memory and peripheral devices under the direct control of single instructions. Each channel has associated with it two instructions to facilitate direct control operations. For Channel W, W INTO MEMORY (WIM) causes a word from a peripheral transmission to be taken from the Channel W buffer register and placed directly in the specified memory location without disturbing any internal registers. MEMORY INTO $W$ (MIW) causes a word to be taken from a specified memory location and placed in the Channel W buffer register to be read out to the currently operating peripheral device connected to the channel. WIM and MIW are preceded by instructions from the EOM group that set up the input/output operation. YIM and MIY instructions function in an analogous manner for channel Y. The general test instruction, SKIP IF SIGNAL NOT SET (SKS) provides the facility for testing error indications and/ or for testing various peripheral device indicators.

Additionally, using any channel including Channels $W$ and $Y$ with interlace, data can be transmitted to and from core storage under channel control. Operation of a channel is initiated by the execution of a sequence of instructions in the central processor. Once started, the channel operates independently of the central processor, automatically transferring each word at the correct time.
Four instructions control the process of transmitting and receiving data between channel peripheral equipment and the central processor. These instructions are:

| EOM | ENERGIZE OUTPUT M |
| :--- | :--- |
| EOD | ENERGIZE OUTPUT TO DIRECT ACCESS |
|  | CHANNELS |
| POT | PARALLEL OUTPUT |
| SKS | SKIP IF SIGNAL NOT SET |

EOM instructions activate one of Channels $\mathrm{W}, \mathrm{Y}, \mathrm{C}$, or D , to select the peripheral device to be used, and to set up the initial conditions of the data transmission, including the peripheral operation to be performed. EOD instructions activate one of Channels E, F, G, or H. The other functions of EOD are similar to EOM. An EOM (EOD) instruction also specifies terminal conditions for an operation.

PARALLEL OUTPUT (POT) sends out to the channel the number of words in the transmission and the address at which the output begins.
SKIP IF SIGNAL NOT SET (SKS) can test the Error indicators, End-of-Transmission indicators, and other input/output control indicators, such as printer end-of-form or card hopper empty.
The general order of use of these instructions for interlaced operation is:

Instruction
EOM

## Function

to address the channel, connect the peripheral device, specify various input/output conditions, and alert the optional channel interlace (see Communication Channel Input/Output)

| Instruction | Function |
| :--- | :--- |
| EOM | to specify the terminal conditions and inter- <br> rupts desired during the transmission |
| POT | to transmit to the channel a word containing <br> the transmission starting address and block <br> length |

Bits 0 through 9 of this latter word contain the ten lower order bits of the word count; bits 10 through 23 contain the 14 bits of the starting address. The second EOM contains the highorder bits of the word count and starting address when needed.

## DIRECT PARALLEL INPUT/OUTPUT

The direct parallel input/output (POT/PIN) facility allows any word in core memory to be presented, in parallel, at any special system connector or applicable standard peripheral connector; or, conversely, allows signals sent to a connector to be stored in any core memory location. EOM and SKS instructions control parallel input/output operations in the same way as in channel operations. POT/PIN instructions also generate or check for correct parity with each word transmitted.

See Direct Parallel Instructions, this section, for a detailed description of parallel input/output.

## SINGLE-BIT INPUT/OUTPUT

EOM and SKS instructions also perform single-bit input/output and testing for special or standard devices. The execution of an EOM transmits a single signal of approximately 1.4 microseconds duration to an external connector and also provides the connector with a 15 -bit address for the destination of this signal. SKS tests whether a similar signal is present on an external connector and skips accordingly. See Single-Bit Transmission, this section, for further description of single-bit input/output.

## DIRECT MEMORY ACCESS SYSTEM

This optional system provides direct transmission between peripheral devices and core memory. Two access paths to the memory module are available. The standard path connects to the central processor; the other path connects to Direct Access Communication Channels on the Direct Memory Access Connection. Direct memory access allows data to be transmitted at the rate of one 24 -bit word every 1.75 microseconds, thus sustaining an input/output rate of 572,000 words (equivalent to 2,284,000 characters) per second in parallel with full-speed computation.

Communication Channels, E, F, G, and H, if present in a system, require the Direct Memory Access System, and therefore, are called Direct Access Communication Channels. Operation of these channels is discussed in Communication Channel Input/ Output, this section.

Note that the Direct Memory Access System may be obtained separately and used to incorporate special-purpose input/output equipment instead of the standard Direct Access Channels. Ex-
ternally controlled and sequenced devices may present data and addresses to the direct access connectors, thus allowing input/output operations or other memory accesses to be performed independently of the computer.

These special input/output systems present an address and various timing and control signals to the connector. External data may be stored in any specified location, or read from any location specified by the external unit. For example, the external equipment may provide an interface register, thereby allowing an entire block of data to be entered into or read from memory. Telemetry data may be automatically decommutated, thus obviating sorting and sequencing within the computer.

## PRIMARY INPUT/OUTPUT INSTRUCTIONS

EOM ENERGIZE OUTPUT M

The major instruction for preparing Channel W (or $\mathrm{Y}, \mathrm{C}$, D) and an attached peripheral device to perform a data transmission or other peripheral activity is the multi-purpose instruction, ENERGIZE OUTPUT M (EOM). It operates in four distinct modes with many functional configurations. These modes are Buffer Control, Input/Output Control, Internal Control, and System Control. In the third and fourth modes, EOM controls and initiates non-communication channel operations such as special systems transmissions. Each of the frequently used EOM instruction configurations has a mnemonic tag used with standard XDS assemblers. These mnemonics appear in this manual with the description of the specified configurations. The different modes of operation are program-selectable by the setting of two bits (10, 11 of octal position 3) within the EOM instruction format:

| Octal <br> Value | Bit Position 10 | Bit Position 11 | Area |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | Buffer Control |
| 1 | 0 | 1 | Input/Output Control |
| 2 | 1 | 0 | Internal Control |
| 3 | 1 | 1 | System Control |

A Buffer Control mode EOM operates essentially as a set-up or preparation facility for data transmissions or other peripheral activities using the channel. The channel to be used, the peripheral unit on that channel, the operation to be performed, and the type of character format to be used are all detailed within this EOM. It also details the use of BCD or binary data transmission, the allowance or not of a leader (as in papertape), and the direction of operation (as in forward direction for magnetic tape). Execution of such an EOM "connects" the specified peripheral unit to the channel. An EOM in this mode can also alert the interlace, which is the optional, automatic buffer control for input/output.

An EOM in the Input/Output mode directs peripheral devices to perform non-transmitting operations such as rewind magnetic tape and upspace the printer. This EOM selects certain channel operations such as interrupt response and input/output terminal function desired. It alerts peripheral devices that a PARALLEL INPUT (PIN) or PARALLEL OUTPUT (POT) instruction follows. It also can give an extension of the word count to 15 bits for the number of words to be transmitted and an extension of the address specification to 15 bits. Without disturbing the associated channel, this EOM can also set up the interlace unit. It is with the input/output mode EOM that the user selects his I/O operation as compatible or extended I/O modes (described later in this section).

This coding sequence initiates such an interlaced channel operation (compatible mode):

| Instruction | Function |
| :--- | :--- |
| EOM (Input/ <br> Output Control <br> Mode) | Alert the interlace |
| POT | transmit starting address and <br> block length to interlace |
| EOM (Buffer <br> Control Mode) | address channel, connect <br> peripheral device, specify <br> various input/output conditions, <br> start transmission |

Initiating an interlaced input/output operation via this sequence of instructions facilitates checkout by allowing the programmer to single-step through this portion of the program. The first two instructions, EOM (Ioc) and POT, set up the interlace with dato address and block length. Therefore, single-stepping through the sequence allows the interlaced channel to complete the input/output operation. When a single EOM (Buffer Control mode) sets up the channel and interlace with a POT instruction following, the programmer cannot step through the sequence since the input/output operation proceeds before the next stepped instruction (POT) places the address and block length in the interlace.

An EOM in the Internal Control mode enables and disables the interrupt system. EOM in this mode also can prepare the system for the selective arming and disarming of the system interrupt levels. This mode does not directly concern the input/output programmer.

An EOM in the System Control mode is specifically coded for a given installation and system. Address capability is 15 bits or 32,768 combinations for these special system designations.

Note: If an interrupt occurs during the execution of an EOM in any mode, no acknowledgement occurs until the completion of the execution of the instruction following the EOM.

The EOD instruction operates in the Buffer Control and Input/ Output Control modes. It refers to Channels E, F, G, and H, when present, and performs the same functions and operations as an EOM on these channels.

SKS SKIP IF SIGNAL NOT SET

The principal instruction for testing the states and responses of data channels and their attached peripheral devices, as well as testing internal and external indicators, is the multi-purpose instruction, SKIP IF SIGNAL NOT SET (SKS). SKS is a "skip class" instruction yielding a decision and transfer capability to all channels, devices, indicators, and systems that require it. It operates in four distinct modes: Special Internal Test, Channel and Device Test, Internal Test, and Special System Test. In the second mode, SKS tests channel-oriented, input/output functions. Each of the frequently used SKS instruction configurations has a mnemonic tag, used with XDS assemblers. These mnemonics appear in this manual with the description of the specific configuration.

These different modes of operation are program-selectable by the setting of two bits ( 10,11 of octal position 3 ) within theSKS instruction format:

| Bit Positions |  | Octal Value | Area | $\underline{\text { Timing }}$ |
| :---: | :---: | :---: | :---: | :---: |
| 10 | 11 |  |  |  |
| 0 | 0 | 0 | Special Internal Test | 1,2 |
| 0 | 1 | 1 | Channel and Device Test | 2,3 |
| 1 | 0 | 2 | Internal Test | 1,2 |
| 1 | 1 | 3 | Special System Test | 2,3 |

In the Channel and Device Test mode, SKS tests a channel for channel Ready (not active), interlace Word Count Equal to Zero, and Error. This mode also tests peripheral devices directly. These include testing indicators in a magnetic tape unit such as Beginning-of-Tape, End-of-Tape, File-Protect Ring present, and End-of-File. For example, an SKS instruction might address an indicator within the printer to determine whether the paper is at the End-of-Form.

In the Internal Test mode, SKS tests whether the interrupt system is enabled or disabled, whether a breakpoint switch is set, and whether Overflow is set.

In the Special Internal and Special System Test modes, SKS tests signals of special configuration as the specific system requires.

## COMMUNICATION CHANNEL INPUT/OUTPUT

## GENERAL INFORMATION

XDS Communication Channels provide fully buffered, input/ output control and transmission, multiplexed or simultaneous with computation. Up to eight data channels can connect to the central processor, all operating independently of each other.

Each channel can control as many as 30 input/output devices and automatically handles character, word assembly and disassembly, input/output parity detection and generation, data transmission to and from memory, and End-of-Transmission detection.

All channels are bi-directional and can communicate with 6 -bit character devices or word devices of up to 24 bits. In the case of character-oriented devices, the program specifies the number of characters to be contained in each word during the transmission.

A channel buffer assembles and disassembles data words as they are transmitted between core memory and the peripheral equipment. The buffer maintains control of operations such as characters per word transmitted and direction of peripheral operation (as in magnetic tape forward/reverse).

A Buffer Control mode EOM or EOD sets up the channel buffer for operation. The execution of this EOM sets the operation controls, places the unit address in the buffer, and initiates data assembly/disassembly. The presence of the unit address activates the buffer, causing it to look for data coming from the peripheral device or from memory, as determined by the unit address.

When in use, a channel interlace controls the transfer of the data words going through the associated channel buffer. This interlace supplies the memory address of data coming from or going to memory and maintains the word count determining the number of words transferred. The terminal interrupts, End-ofRecord and Zero Word Count, come from the interlace and are under its control. The interlace controls input/output termination functions during interlaced operation.

Two EOM instructions and a POT instruction alert and set up a channel interlace. The first EOM alerts the interlace, that is, activates the interlace and instructs it to expect a word count and starting address to be sent to it by the POT instruction. The second EOM is an Input/Output mode EOM that specifies the interrupt and the terminal function to be used. This EOM also can specify a 15 th address bit and five more high-order word count bits expanding the word count from 10 bits to 15 . This sequence is written: EOM (Alert), EOM (I/O), and POT. When the channel buffer is being set up at the same time, the buffer control EOM can alert the interlace. When the buffer is already set up, during a continuing $\mathrm{I} / \mathrm{O}$ operation, the programmer may use the I/O EOM, ALERT CHANNEL (00250000), to alert the interlace.

When the programmer does not desire to program the Extended Mode with the input/output terminal functions, interrupts, and additional count or address, only the EOM (Alert) and the POT are necessary to set up the channel interlace (Compatible mode).

In the Extended Mode, the eight channels are programmed in the same way, though there is a distinction between Channels W through $D$ and Channels $E$ through $H$. The former group are TimeMultiplexed Channels; the latter are Direct Access Channels.

The Time-Multiplexed Channels use the memory logic of the central processor to facilitate input and output of data words. The transfer of each word between a time-multiplexed channel buffer and memory requires two memory cycles. During this time, computation stops in the central processor. Priority for the use of the word input/output logic is in the order: Channel D, C, Y, W. Any Time-Multiplexed Channel operating with interlace has priority over the central processor for memory access.
Each Direct Access Channel has its own independent memory logic. When memory access is needed to read or store a data word, computation stops for one cycle. When two or more Direct Access Channels require memory access simultaneously, determination of priority is as described in Appendix A-19.

Transmission to and from Direct Access Channels and core memory are under the control of the channel. At the onset of each memory cycle, the control unit interrogates all Direct Access Channels to determine whether any channel requires a transfer to or from computer memory; each channel gets priority on the basis of need. If, during a channel transmission, a transfer to or from computer memory is to take place, the computer connects the memory bank to the selected Direct Access Channel. If, simultaneously, the computer requires access to the same memory bank, the channel takes precedence and there is a delay of one memory cycle. If the computer is not accessing the same memory bank as the direct access channel, the transfer takes place without affecting computation speed. Thus, internal computation and direct access channel transmissions occur simultaneously and independently when the computer and channel are accessing separate memory banks. Channel control logic permits the transfer of only one word per memory cycle to and from the computer memory independent of the number of operating channels connected to the computer. Thus, the maximum transfer rate for the channel system is equal to one word every memory cycle, or approximately 572,000 words per second, or in excess of two and one-quarter million characters per second for direct access channels.

## COMMUNICATION CHANNEL DESCRIPTION

Figures 4-1 and 4-2 contain block diagrams of the channels, the functional control of information between the channels, the Data Multiplexing System, the memory bank, and the external devices.

Up to 30 peripheral devices may be connected to one channel. Each of these devices has a unique, two-digit, octal address by which it is selected for an input/output operation. To select the peripheral device, the program loads the proper unit address into the 6-bit Unit Address Register (UAR) in the channel buffer. This address selects both the device and, if appropriate, the function to be performed. Placing a non-zero unit address in the Unit Address Register "connects" the peripheral unit addressed to the channel and it becomes "active". When the UAR contains a zero address, or any time that a terminal or initial condition clears the contents of UAR, the channel is "inactive." The zero in UAR also means that it is not connected to a peripheral unit.

When the channel and the peripheral unit to be used have been connected, the channel must have information pertaining to the location in memory of the data to be transmitted or received and pertaining to the number of data words in the transfer.

Figure 4-1. XDS 930 Time-Multiplexed Communication Channel, Block Diagram

## TIME-MULTIPLEXED CHANNEL REGISTERS

In the Time-Multiplexed Channels $W$ through $D$, there are two registers important to the programmer, the Word Assembly Register (WAR) and the Single-Character Register (SCR). The WAR, a 24-bit, word-sized buffer, contains the word of data actively being received or transmitted during an input or output operation. During input, 6-bit characters (plus parity) enter the Single-Character Register where the channel buffer assembles them, one at a time, into the WAR. Then the completed word is placed in memory. Depending on the number of characters per word specified, the word assembled and placed in memory during input has the form:

Two characters per word mode

Three characters per word mode

Four characters per word mode

| 1 st | 2nd | 3rd | 4th |
| :---: | :---: | :---: | :---: |
| 0 |  |  |  |

The unfilled character positions contain unpredictable data. When assembled during a single-word operation, a WIM instruction places the word into memory. Under interlace control,
the interlaced channel automatically places the word in memory when assembled.
When the end of an information record is detected by a buffer, the buffer automatically disengages from the device and is then "ready" for another operation. The buffer logic is reset, except that the state of the error indicator is maintained and the last word of the input is still in the word register. If the number of characters in the input record was not a multiple of the number of characters assembled into each computer word, then zeros are automatically forced into the least significant positions of the last word. This last word can then be stored in memory by a BUFFER INTO M WHEN READY WIM or YIM instruction after the buffer has disengaged. If the number of characters in the input record was a multiple of the number of characters assembled into each computer word, then the word remaining in the $W$ buffer is either the last group of characters from the input device, if they were not previously transferred to memory by a BUFFER INTO M WHEN READY WIM or YIM, or zeros if the last group of characters had been transferred to memory. In either case, it is safe to issue one such instruction after the buffer has disengaged without "hanging up" the computer.

During output, words come from memory into the WAR where the channel buffer disassembles them into the SCR one 6-bit character at a time. Depending on the characters per word mode specified, the 6-bit characters within the word are output as follows:

## Function

Output one character from bits 0 through 5
Output two characters from bits 0 through 5, 6 through 11
Output three characters from bits 0-5, 6-11, 12-17
Output four characters from bits 0-5, 6-11, 12-17, 18-23
$\frac{\text { Mode }}{\text { One character per word }}$
Two characters per word

Three characters perword
Four characters perword

As required, the characters are transferred into the SingleCharacter Register and output with generated parity. After each character transfer, the word in the WAR is shifted left six bits to be ready for the next transfer. Only those characters needed from each word are used; when required, a new word is brought to the WAR for the next character. For special applications, a Time-Multiplexed Channel may be equipped with a 12-or 24-bit Single-Character Register. The external device which has a character size greater than 6 bits specifies to the channel what its size is, 12 or 24 bits. Standard 6-bit devices are unaffected by the installation of a wider SCR.

## Interlace Registers

A channel interlace contains two working registers, the Word Count Register (WCR) and the Memory Address Register (MAR). in the set-up sequence -- EOM, EOM, POT -- for an interlaced input/output operation, the POT instruction transmits to the interlace a data word made up of the word count (that is, length) and the starting address of the data block. The 15-bit Word Count Register (WCR) contains the data word count during a data transfer. The number of data words is decremented by one and the new count replaces the old one in the WCR for each word transmitted.

The count is assembled into the WCR from two places: the least significant 10 bits is from the "POTted" word and the most significant 5 bits is from the "HI COUNT" field of the second EOM. The form of the "POTted" word is:

When the word count is equal to zero, the transmission is complete. During output, this causes a termination; during input,
the interlace allows any further data to fill the channel buffer and generates the End-of-Word interrupt, if enabled.
The Memory Address Register (MAR) contains the starting destination or source address in memory of the transmitted data. The memory locations to or from which data words are to be transmitted enter the MAR at the same time the word count does. During transmission of data, the interlace increments the contents of the MAR after each word as it decrements the contents of the WCR. These two registers provide the interlace control of block transmissions. The highorder 15 th address bit comes from the second EOM, also.

## DIRECT ACCESS CHANNEL REGISTERS

In the Direct Access Channels $E$ through $H$, two other important registers are the Word Assembly Register (WAR) and the Input/Output Register (IOR). The Word Assembly Register is a 24-bit word-sized buffer which, during a transmission, contains the information actively being transmitted to, or received from, the external device. Information is assembled into, or disassembled from, the WAR in one of four character sizes, $\boldsymbol{j}^{2}, 8$, 12 or 24 bits. The 6 -bit mode is the normal mode of operation. A device with a larger character size will send the channel a signal to indicate its character size. It is the programmer's responsibility to select a character/word count suitable for the character size.
(Time-Multiplexed channels can handle only 6-bit characters, standard. There are, however, two options which will increase the acceptable character size to 12 bits and to 24 bits. As with the DACCs the external device signals the TMCC with its character size.)

When receiving 6-bit characters from a peripheral device (operation is similar for other character sizes), the first character of a word enters the WAR into bit positions 18 through 23. When the WAR receives the next character, the first

Figure 4-2. XDS 930 Direct Access Communication Channel, Block Diagram
six bits in positions 18 through 23 shift into bit positions 12 through 17 and the incoming character is placed into bit positions 18 through 23. The next incoming character causes the two 6 -bit characters in bit positions 12 through 23 to be shifted to bit positions 6 through 17 and the incoming character is placed into bit positions 18 through 23 . The next character causes another 6-bit left shift and then the character is placed in the vacated bit positions 18 through 23. At this point, there are 24 bits completely filling the WAR. This information is now copied into the IOR to be placed into the proper memory location.
The above procedure occurs when the programmer specifies four characters per data word for the data transmission. If the specification is three characters, the data word contains three 6-bit characters in bit positions 6 through 23 and unpredictable information in bit positions 0 through 5 are transmitted to the IOR. The next incoming character is accepted as the first of another set of three characters. If the programmer specifies two characters, the data word contains two 6-bit characters in bit positions 12 through 23 and random data in bit positions 0 through 11 are transmitted to the IOR. If the specification is one character, the data word transmitted to the IOR contains only one character in bit positions 18 through 23. When transmitting data using the character format mode, characters are taken from the WAR from the most significant end. If the programmer specifies one character per word, the 6-bit character in bit positions 0 through 5 is transmitted to the external device and then another full word of information is received from the IOR. If the programmer specifies two characters per word, the 6 -bit character in bit positions 0 through 5 is transmitted. Then the contents of bit positions 6 through 23 shift left into bit positions 0 through 17, the new 6 -bit character in bit positions 0 through 5 is transmitted and another word is accepted from the IOR to be processed. If the programmer specifies three characters, the 6-bit character in bit positions 0 through 5 is transmitted. The contents shift left six bits and the new contents of bit positions 0 through 5 are transmitted. The contents shift left six bits again and the third character from bit positions 0 through 5 is transmitted. Then another word is received from the IOR to be processed. If the programmer specifies four characters, the above process continues to one more 6-bit left shift and the final six bits of the word are transmitted before the next word is accepted from the IOR.

The Input/Output Register (IOR) is a 24 -bit register which is a full-word buffer between the WAR and memory. The Direct Access Channel control unit places words into the IOR, awaiting their transfer to the WAR to be output. During input, the IOR receives full words from the WAR and places them into memory under control of the word count and memory address being used in the transmission. During multiple data word transfers, the WAR and the IOR simultaneously contain data information.

## COMMUNICATION CHANNEL PROCRAMMING

The ENERGIZE OUTPUT $M$ (EOM) used in the Buffer Control mode addresses and connects the specified Channel $W, Y, C$, or $D$, and selects the desired unit address. The detailed instruction format is:

Bit Octal Octal
Designation Position Value

## Function

BI

B2

O6-7

Bit positions 10 and 11 contain the EOM mode indicator for the Buffer Control mode.
Bit positions 1 and 17 specify the channel to be activated.

Channel $W$ is numbered 00 , Channel Y is 01 , Channel $C$ is 10 , and Channel $D$ is 11.

Bit positions 3 through 8 contain 02, the instruction code for EOM.

A l-bit in position 9 alerts the buffer interlace.

Bit position 12 specifies the direction in which the peripheral device will operate. A "0" specifies the forward direction. A "l" specifies the reverse direction.

Bit position 13 specifies whether the device should be started with a leader as in paper tape. A "0"specifies a start with leader. A" 1 " specifies a start without leader.

Bit position 14 specifies the mode of character format. A " 0 " specifies BCD format. A"1" specifies Binary format.

Bit positions 15 and 16 specify the number of characters to be assembled into, or disassembled from, each transmitted word. One character per word is specified by 00 (octal 0 ), two by 01 (octal 2), three by 10 (octal 4) and four by 11 (octal 6).

Bit positions 18 through 23 specify the unit and the function to be performed with that unit.

The EOD instruction used in the Buffer Control mode alerts and connects the specified Direct Access Channel (E, F, G, H) and the desired unit address. The instruction format is:

All other indicators in the EOD are identical with EOM and function in the same way.

## STANDARD EOM AND EOD CHANNEL INSTRUCTIONS

Several EOM and EOD function configurations have standard uses. These have standard, assembler-type mnemonics and are separate instructions.

ALC ALERT CHANNEL

ALC alerts the channel interlace. This instruction does not disturb the channel buffer in any way. ALC has no effect on W or Y Buffers without interlace.

The channel Alerts are:

| Mnemonic | Alert Channel | Instruction |
| :---: | :---: | :---: |
| ALC 0 | W | 00250000 |
| ALC 1 | Y | 00250100 |
| ALC 2 | C | 20250000 |
| ALC 3 | D | 20250100 |
| ALC 4 | E | 00650000 |
| ALC 5 | F | 00650100 |
| ALC 6 | G | 20650000 |
| ALC 7 | H | 20650100 |

Registers Affected: None
Timing: 1

DSC DISCONNECT CHANNEL

| 0 |  | 02 |  | 00000 |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 0 | 2 | 3 | 1 | 8 | , 1 |

DSC disconnects the channel. It unconditionally sets the Unit Address Register to 00 regardless of whether the channel is currently addressing a device. This instruction disconnects any device which may be connected to the channel. It also unconditionally makes the channel Ready (Inactive) and clears the Error indicator.

ASC alerts an interlaced channel so the PIN instruction that follows can store the contents of the Memory Address Register. This instruction affects the operation of the channel in no other way. See Direct Parallel Instructions, this section, for a detailed discussion of PIN

ASC is always used in conjunction with PIN to determine the current status of a peripheral operation being performed by the selected channel. The two instructions are written together:

ASC $n$
PIN m, $x$
When the program executes these two instructions, the contents of the effective memory location designated by the PIN instruction are:

| Bit Positions |  | Contents |
| :---: | :---: | :---: |
| 0 through 9 |  | Zero |
| 10 through 23 |  | Contents of channel's Memory Address Register |
| Mnemonic | Channel | Instruction |

| rs Affected: N |  | Timing: |

TOP TERMINATE OUTPUT OF CHANNEL

When the last word of a block enters the channel, TOP terminates channel output. After the execution of this instruction, the following occurs. When the channel buffer delivers the last character to the peripheral device, the buffer disconnects.

TOP always terminates a non-interlaced channel output operation. It may be used with all communication channels if the particular function selected is terminal function 11 but no further data output is required (see Terminal Functions, this section).

| Mnemonic | Terminate Output <br> on Channel |  |
| :---: | :---: | :---: |

|  |  | 20614100 |

Registers Affected: None Timing: 1

## COMPATIBLE/EXTENDED INPUT/OUTPUT MODES

The termination of an I/O operation and the interrupts that may be associated with that termination fall into two classes: Compatible and Extended. The choice of one of these two "modes" of input/output operation determines how the system behaves when the termination of an I/O operation occurs.

As mentioned in Section III, Interrupt System, interrupts occurring at the same level (e.g., location 30, 31, etc.) can have different names (e.g. , Count Equal Zero and End-ofWord). These names reflect the different I/O mode in operation when the interrupt occurs. The differences include the timing of interrupt occurrence relative to the I/O operation and type of interrupt requested.

The Compatible mode of operation for channels W, Y, C, D is directly compatible with the XDS 920 Computer mode of I/O operation. The types of interrupts that can be requested are the End-of-Word and End-of-Transmission interrupts.
The Extended mode for all channels expands the I/O capabilities to include the "terminal functions" discussed below. The types of interrupts that can be requested are the Count Equal Zero and End-of-Record interrupts.

The $1 / O$ mode is selected in the Input/Output EOM (EOD) via bit 12, the Interrupt Arm bit. A 0 -bit makes the system operate in the Compatible mode; a l-bit sets the system in the Extended mode.

In particular, the Interrupt Arm (IA) bit determines whether any of the Extended functions operate; that is, a " 0 " in IA means that the other Extended mode controls, bits 13, 14, 15 and 16 , have no effect.

## INPUT/OUTPUT CLASS EOM/EOD

The Input/Output EOM (EOD) selects the I/O operation mode. When the Extended mode is selected, this EOM also selects (arms) which interrupts are to be operational and selects the desired terminal function. This EOM applies to Channels W, Y , C, and D. EOD applies to Channels E, F, G, and H.

Bit

Designation | Octal Octal |
| :---: |
| Position Value |

## Function

Bit positions 0, 1, 2, and 17 are not used with this EOM.

Bit positions 3 through 8 contain 02/06, the instruction code for EOM/EOD.

Bit positions 10 and 11 contain the EOM/EOD indicator for the Input/ Output control mode.

Bit position 12 selects the mode of I/O operation. A " 0 " specifies the Compatible mode. The operation of bits $13,14,15$, and 16 aredisallowed. Channels W, Y, C and $D$ operate in this mode which is completely XDS 920compatible. If interrupts are required, the user enables the Interrupt System, thus enabling and arming the End-of-Word and End-of Transmission interrupts.
A" 1 " specifies the Extended mode. All channels can operate in this mode. This allows the use of bits 13,14 , 15, and 16. If interrupts are required, the userarms the associated ones by placing 1 -bits in bit 13 and/or 14. The "terminal function" to be used is selected via bits 15 and 16 .

Note: A 1-bit in 13 and/or 14 does the following:

1. Arms that interrupt during this complete $\mathrm{I} / \mathrm{O}$ operation; disconnecting this channel disarms the interrupt.
2. Once armed by bits 13 and/or 14, the interrupt can be enabled or disabled by the Enable/ Disable feature of the Interrupt System. If a channel generates an extended mode $1 / O$ interrupt while the system is disabled, the designated interrupt level goes to the Waiting state. When the program again enables the interrupt system, the interrupt goes to the Active state when its priority allows.

Direct Access Communication Channels operate only in the Extended mode; therefore, a DACC does not examine bit 12, but assumes it to be a l. Note that with the complete omission of this second EOM, a DACC operates in the IORD or terminal function 00 mode.

| Bit <br> Designation | Octal <br> Position | Octal <br> Value | Function |
| :---: | :---: | :---: | :---: |
| ER |  | 2 | Bit position 13 controls the arming of the End-ofRecord interrupt. A l-bit arms the interrupt. A 0bit disarms the interrupt. |
| ZC |  | 1 | Bit position 14 controls the arming of the Zero Word Count interrupt. A l-bit arms the interrupt. A 0 -bit disarms the interrupt. |
| FC | O5 | 0 2 4 6 | Bit positions 15 and 16 specify the terminal condition function to be performed with the transmission These are defined in the next topic in this section. |
| A |  |  | Bit position 18 is the high-order address bit. |
| HI Count |  |  | Bit positions 19 through 23 contain the most significant four bits of the 15bit word count. These positions specify a word count greater than 1023. |

## TERMINAL FUNCTIONS; EXTENDED MODE

A 2-bit function code in the Input/Output EOM (EOD) controls the termination of input/output operation in the extended mode. These functions are described below with the letter $C$ representing the specified word count of the transmission.

|  |  | Bit <br> Configuration | Octal <br> Value |
| :---: | :---: | :---: | :---: |
| IORD | INPUT/OUTPUT OF A RECORD AND DISCONNECT | 00 | 0 |

Input
Read $C$ words. If $C$ equals zero before the End-of-Record is detected, the rest of the record is ignored. At the End-of-Record, the peripheral device is disconnected and the channel becomes inactive.

Output Write C words. When C equals zero, output is terminated (i.e., the device is signaled that the last characters have been transmitted). When the peripheral device has generated the end of record and, if necessary, checked the validity of the record, it sends an End-of-Record response to the Channel buffer. When received by the buffer, the End-of-Record signal generates an End-of-Record interrupt (if armed) and disconnects the channel.

The line printer generates the End-ofRecord response when it completes the printing of a line. If the printer encounters any print errors or faults, it sends a signal to the channel that sets the channel error indicator; this can occur since the printer has
not disconnected from the channel. The IORD is useful when the program is to print several lines and the program is not otherwise to use the channel between lines. When the printer completes each line, it causes an End-of-Record interrupt (assumed to be armed), notifying the program that it can immediately transmit the next paper control instruction and the next line image.
The unbuffered card punch operates similarly. It generates the End-of-Record response after punching each row. If any faults occur during the punching of the entire card, the card punch sends a signal to the channel that sets the channel error indicator; this occurs after punching the last row (row 9).
NOTE: A program should not use IORD with devices that do not have End-of-Record conditions on input (e.g., typewriter) or generate End-of-Record responses upon output termination, (e.g., devices such as the paper tape punch and typewriter). These devices do terminate output but give the program no indication when they receive the last characters.

|  | Bit <br> Configuration | Octal <br> Value |
| :--- | :---: | :---: | :---: |
|  |  |  |
| INPUT/OUTPUT UNTIL SIGNAL |  |  |
| THEN DISCONNECT | 01 | 2 |

Input Read $C$ words. When $C$ equals zero or when the End-of-Record is encountered, the device is disconnected and the channel becomes inactive. If the channel disconnects because of a zero count, an EOR interrupt (if armed) will be generated in addition to the count equal zero interrupt. If both are armed, $\mathrm{C}=0$ will occur first.

Output Write C words. When C equals zero and when the last character has been transmitted, the channel disconnects the device and becomes inactive. If an End-of-Record signal is received before the count reaches zero, the channel will disconnect immediately.

NOTE: The IOSD is designed for use on devices which are normally operated on the basis of the word count only. Typewriters and paper tape devices are of this type, as are the printer and card punch when the user does not wish to stay connected until the operation is complete.

IORP INPUT/OUTPUT OF A RECORD AND PROCEED

10
4
Input Read $C$ words. If the channel counts $C$ down to zero before the peripheral device encounters the End-of-Record (EOR), the channel ignores the rest of the record (to the End-ofRecord). When the peripheral device sends the End-of-Record signal to the channel, the channel sets its End-of-Record Indicator; this signal sets the End-of-Record interrupt (if armed). The channel does not disconnect. The channel is now in an "Inter-record" condition.

When the peripheral device is magnetic tape, the tape continues to move when the tape handler encounters the End-of-Record. The End-of-Record occurs when the tape readheads encounter tape gap; this also causes a Tape Gap signal to "come high". If the program executes a new read tape or scan tape EOM during the inter-gap time (approximately. 75 millisecond while the Tape Gap signal is high), the tape remains in motion and proceeds to read or scan the next record. If the program executes no such EOM before the Tape Gap signal drops, the channel disconnects and the tape comes to a stop. No additional interrupt occurs. This is the only condition that causes a channel to disconnect automatically.
All other input devices remain connected until the program takes further action. The paper tape reader remains in motion; the program should issue a "disconnect channel" instruction if the program is not reading any more tape. To proceed after the End-of-Record occurs, the program first executes a Buffer Control mode EOM to re-initialize the Channel Unit Address Register and then reloads the interlace portion of the channel (the program can alert the Interlace via the Buffer Control EOM). Otherwise, the channel immediately terminates any attempt to use its interlace portion since the channel is aware that it is still active and in the End-of-Record condition. When the program continues from an Inter-record condition, the program should use an extended mode terminal function. An IORP should not be used to read devices which do not have EOR signals (e.g., the typewriter and paper tape reader).
Output Write C words. When the channel interlace counts $C$ down to xero, the Interlace notifies the channel buffer that it has received the last word that is to be output; when the buffer outputs this last word, it sends a signal to connected peripheral device indicating that the device has the last word now. When the peripheral device "receives, outputs and checks the validity of" this last word, it sends an End-of-Record response to the channel buffer. When received by the buffer, the End-of-Record signal generates an End-ofRecord interrupt (if armed) and sets the Interrecord indicator; the channel does not disconnect.
When the peripheral device is magnetic tape, the tape continues to move after it signals End-of-Record. As in reading tape, the signal causes the Tape Gap signal to come high. If the program executes a new write tape or erase tape EOM during the inter-gap time (approximately one millisecond), the tape remains in motion and proceeds to write or erase a new record. If the program executes no such EOM before the Tape Gap signal drops, the channel disconnects and the tape comes to
a stop. No interrupt occurs at this time. This is the only condition which causes a channel to disconnect automatically.
To proceed after the End-of-Record occurs, the program first executes a Buffer Control mode EOM to re-initialize the Channel Unit Address Register and then reloads the interlace portion of the channel (the program can alert the Interlace via the Buffer Control EOM). Otherwise, the channel immediately terminates any attempt to use its interlace portion, since the channel is aware that it is still active and in the End-of-Record condition. When the program continues from an Interrecord condition, the program should use an extended mode terminal function.

A program should not use IORP with devices that do not generate End-of-Record responses upon output termination; such devices are paper tape and typewriter. These devices do terminate output but give the program no indication when they receive the last characters.

The IORP should also not be used with the printer and card punch since these devices expect the channel to disconnect after they send EOR.

## IOSP INPUT/OUTPUT-UNTIL SIGNAL THEN PROCEED

| Bit <br> Configuration | Octal <br> Value |
| :---: | :---: |
|  |  |

Input Read $C$ words. If the channel counts $C$ down to zero before the peripheral device encounters the End-of-Record, the channel generates a Count Equals Zero interrupt (if armed). The program should reload the interlace portion of the channel to continue reading the record. As far as the peripheral device knows, nothing happens at this time. Failure to reload the Interlace before the peripheral device sends enough characters to overfill the channel buffer causes a rate error; this sets the channel error indicator.

When the peripheral device encounters the End-of-Record, IOSP operates identically like the IORP command.

Output Write $C$ words. When the channel counts $C$ down to zero, the channel generates a Count Equals Zero interrupt (if armed); the channel does not terminate output. The programshould reload the interlace portion of the channel to continue writing in the same record. Failure to reload the Interlace before the buffer transmits all of the characters in its registers and before the peripheral device requests the next character from the buffer results in a rate error; this sets the channel error indicator. If the program executes a TERMINATE OUTPUT (TOP) instruction after the channel has counted $C$ down to zero, the channel terminates the output and operates identically like the IORP from this point on.

## CHANNEL AND DEVICE SKS

The Channel and Device Test mode SKIP IF SIGNAL NOT SET (SKS) tests the indicators in a channel as well as devices attached to it. To test the channel, use unit address 00 . The instruction format is:

## CHANNEL TESTS

$40 \quad \mathrm{Ol-O} 20 \quad$ Bit positions 3 through 8 contain 40, the SKS instruction code.

01 O3 Bit positions 10 and 11 contain the mode selection.

C1 O3 4 BitsC1, C2, C3, used as an
C2 O0 2 octaladdress, specify the
C3 O5 1 channel to be tested. Channel $W$ is 0 , Channel $Y$ is 1 , and so on, Channel H being 7 .

R
Test for ready. A l-bit selects the test. Skip if Ready or Inactive.

C $\begin{array}{llll}\mathrm{O} & 2 & \text { Test if indicator for Word }\end{array}$ Count Equal to Zero is set. A l-bit selects the test. Skip if word count zero.
E . 1 Test for error indicator reset. A l-bit selects the test. Skip if no error.

4 Test for Inter-record condition.
$00 \quad$ Bit positions 18 through 23 are zero to specify a channel test. Each of these tests causes a skip when the test condition is true.

## STANDARD SKS INSTRUCTIONS

Several SKS function configurations have standard uses. These have standard, assembler-type mnemonics and are always used as shown.

## CAT CHANNELACTIVE TEST;

SKIP IF CHANNEL NOT ACTIVE

If the channel is ready to accept a new input/output instruction, the computer skips the next instruction in sequence and executes the following instruction. If the channel is active, or in the process of disconnecting a peripheral unit, the computer executes the next instruction in sequence.

| Channel <br> Mnemonic |  |  |
| :---: | :---: | :---: |
|  | W Test | Instruction |
| CAT 1 | Y | 04014000 |
| CAT 2 | C | 04014100 |
| CAT 3 | E | 24014000 |
| CAT 4 | F | 24014100 |
| CAT 5 | G | 04054000 |
| CAT 6 | H | 24054100 |
| CAT 7 | None | 24054000 |
| Registers Affected: |  | Timing: 2, if no skip |
|  |  | 3, if skip |

The following XDS920-compatible instructions make the identical test as the above instructions on Channels W and Y ;

| BRTW | 04021000 | W BUFFER READY TEST |
| :---: | :---: | :---: |
| BRTY | 04022000 | Y BUFFER READY TEST |
| Registers Affected: None | Timing: 1, if no skip |  |
| 2, if skip |  |  |

The indicator that CAT tests is reset only by the next EOM that connects and alerts the same channel.

## CET CHANNEL ERROR TEST;

SKIP IF NO ERROR ON CHANNEL

CET tests the error indicator in the channel for being in the set condition. If the error indicator has not been set, the computer skips the next instruction in sequence and executes the following instruction. If the error indicator has been set, the computer executes the next instruction in sequence.

| Mnemonic | Channel Error Test | Instruction |
| :---: | :---: | :---: |
| CET O | W | 04011000 |
| CET 1 | Y | 04011100 |
| CET 2 | C | 24011000 |
| CET 3 | D | 24011100 |
| CET 4 | E | 04051000 |
| CET 5 | F | 04051100 |
| CET 6 | G | 24051000 |
| CET 7 | H | 24051100 |
| Registers Affected: |  | Timing: 2, if |

The following XDS 920-compatible instructions make the identical test of Channels $W$ and $Y$ :

| BETY | 04020020 | Y BUFFER ERROR TEST |
| :--- | :--- | ---: |
| BETW | 04020010 | W BUFFER ERROR TEST |
| Affected: | None | Timing:1, if no skip <br> $\quad 2$, if skip |

The indicator that CET tests is reset only by the next EOM that connects and alerts the same channel.

SKIP IF CHANNEL WORD COUNT IS ZERO

CZT tests whether the contents of the Word Count Register in the channel have been reduced to zero. If the contents of WCR are zero, the computer skips the next instruction in sequence and executes the following instruction. If the contents of the WCR are non-zero, the computer executes the next instruction in sequence.

The indicator that CZT tests is reset only by a POT instruction to set up the word count and data address in the same channel.

## CIT CHANNEL INTER-RECORD TEST;

SKIP IF INTER-RECORD INDICATOR IS SET

CIT tests the Inter-record indicator in the selected channel. If the Inter-record indicator is set, the computer skips the next instruction in sequence and executes the following instruction. If the indicator is reset, the computer executes the next instruction in sequence. (See IORP instruction description under TERMINAL FUNCTIONS for Inter-record definition).

| Mnemonic | Channel Inter- <br> Record Test | Instruction |
| :---: | :---: | :---: |
|  | W | 04010400 |
| CIT 0 | Y | 04010500 |
| CIT 2 | C | 24010400 |
| CIT 3 | D | 24010500 |
| CIT 4 | E | 04050400 |
| CIT 5 | G | 04050500 |
| CIT 6 | H | 24050400 |
| CIT 7 |  | 24050500 |
| Registers Affected: None |  | Timing: 2, if no skip |

The Inter-record indicator is set only during extended mode operation when using a Proceed Function; the indicator is set for an inter-record or zero count condition. The indicator is reset by the next alert and connect EOM.

## DEVICE TESTS

The SKIP IF SIGNAL NOT SET (SKS) below, used in the Channel and Device Test mode, tests the condition of the peripheral devices in the system directly. The peripheral device sections contain the individual instruction descriptions.

Cl

| C2 | O0 | 2 |
| :--- | :--- | ---: |
| C3 | O5 | 1 |
| 40 | O1-O2 | 40 |

01

Unit Tests
O4-O5

Unit Address O6-O7

Bit positions 9, 1, and 17 are used as an octal digit to specify the channel.
Channel $W$ is 0 , Channel $Y$ is 1 , and so on.

Bit positions 3 through 8 contain the SKS instruction code 40.
Bit positions 10 and 11 contain the mode selection.
Bit positions 12 through 16 select the particular test and are system dependent.
Bit positions 18 through 23 specify the unit address.

## Single-word data transfer via channels w and y

## INSTRUCTIONS

Channels W and Y can be programmed as single-word input/ output buffers. Data transfer is performed under direct program control or with the aid of the interrupt system. Interlace is not used with these instructions.

The following two instructions perform data transfer using Channel W.
MIW MEMORY INTO CHANNEL W WHEN EMPTY

MIW transfers the contents of the effective memory location into the Channel $W$ word buffer. If necessary, the central processor "hangs up" until the buffer is empty and ready to accept the data word.

The $W$ buffer must be connected to the desired peripheral device by a previous "connect" EOM instruction that selects the buffer, the unit address, and all appropriate control functions.

Registers Affected: None
Timing: $2+$ wait

WIM transfers contents of the Channel W word buffer into the effective memory location. If necessary, the central processor "hangs up" until the buffer is full and ready to deliver the data word.

Registers Affected: M
Timing: 3 + wait

MIY MEMORY INTO CHANNEL Y WHEN EMPTY

MIY transfers the contents of the effective memory location into the Channel $Y$ word buffer. If necessary, the central processor "hangs up" until the buffer is empty and ready to accept the data word.

Registers Affected: None Timing: $2+$ wait

YIM CHANNEL Y INTO MEMORY WHEN FULL

YIM transfers the contents of the Channel Y word buffer into the effective memory location. If necessary, the central processor "hangs up" until the buffer is full and ready to deliver the data word.

Registers Affected: M
Timing: $3+$ wait

## SINGLE-WORD OPERATIONS

The single-word buffer operations are used in two ways. Data words transfer between the channel and memory under direct program control. The "connect" EOM and the input or output channel instruction are in sequence and the computer "hangs up" until the buffer is ready to perform the transfer. This delay is usually due to buffer tie-up while the buffer is actively transmitting or receiving the previously requested data word.

Use of the priority interrupt system eliminates the tie-up of the central processor. The interrupt system allows the program to connect the device to be used in the transfer, to enable the interrupt, and then to continue processing in the main program. When the buffer is ready to receive from, or transfer to, memory, the End-of-Word interrupt to the corresponding interrupt location notifies the program that the buffer is Ready. A service routine entered via a BRANCH AND MARK PLACE (BRM) instruction in the appropriate interrupt location processes the interrupt. This routine contains the instruction (MIW or WIM, for example) that can execute immediately without computer tie-up.

During single-word operations, a parity error or incorrect timing error sets the buffer error indication in the channel. The incorrect timing error occurs when characters enter the buffer during input before the removal of the previous word; during output, buffer error indication occurs if characters are needed for output before the buffer receives the next word. The transmission does not terminate upon detection of any of these errors.

The interrupt system can detect an End-of-Record termination. During output, use of TERMINATE OUTPUT (TOP) after the final MIW (MIY) causes an interrupt to the appropriate End-ofTransmission location when that final data word has been processed by the buffer. This interrupt takes the place of the End-of-Word interrupt; the End-of-Transmission condition inhibits the End-of-Word interrupt. During input, the End-ofTransmission interrupt is sent to the End-of-Transmission location when the End-of-Record is detected. During input from devices which do not generate an End-of-Record, an EOM disconnects (DSC) the channel to terminate the transmission. This termination generates no End-of-Transmission interrupt.

## EXAMPLE: WIM

This program reads a block of binary paper tape of any length, using the W buffer without interlace. There is an integral multiple of four characters in the block. This subroutine uses the End-of-Word and End-of-Transmission interrupts of the W buffer and reads data into memory beginning in a table at location 1024.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| H | PZE |  | This is an assembler instruction used to reserve the entry location by filling H with Zero. |
|  | EIR |  | This instruction enables the interrupts. An End-of-Word interrupt will be received after each word is assembled in the $W$ buffer. |
|  | RPT | 0, 1, 4 | This instruction initiates the paper tape read on Channel W, four characters per word (see Paper Tape Input/ Output, this section). |
|  | BRR | H | Return to the main program while awaiting the filling of the buffer with the first word read from tape. |
| TABLE | 00002000 |  | This location contains the input table starting address. |
| When the buffer fills with the first word, it generates the End-of-Word interrupt to location 31. |  |  |  |
| 31 | BRM | H1 | This branch and mark instruction transfers to the read routine. |
| H1 | PZE |  | Reserved entry location. |
|  | WIM | * TABLE | This instruction transfers the contents of the W buffer into the location specified in the contents of location TABLE. The * indicates indirect addressing. If desired, indexing can be used. |
|  | MIN | TABLE | This instruction increments the location for the next input word. |
|  | BRU | *H1 | This instruction transfers indirectly back to the main program to await the next End-of-Word interrupt and clears the currently active interrupt. |

The above procedure continues until the end of the block. When gap is detected, the remaining character positions of the word being assembled in the buffer fill with zeros, and the End-of-Transmission interrupt to location 33 inhibits the End-of-Word interrupt.

| BRM | H2 | This instruction transfers and marks to location H 2. |
| :--- | :--- | :--- |
| H2 |  |  |
| BET | 0 | This instruction reserves an entry location. <br> This instruction tests for the occurrence of an error <br> during the input operation If there were none, the <br> next instruction is skipped and the following one is <br> executed. |
| BRM | ERR | This instruction transfers to an assumed error routine. |
| BRU | This instruction returns to the main program. The read <br> operation is complete. |  |

Since in this example the input record has integral word-length, no characters are in the buffer when the End-of-Record is reached. If there are one, two, or three characters in the buffer when it detects the gap, an additional WIM has to be executed to place these characters into memory.

## direct parallel input/output instructions

Two instructions, PARALLEL OUTPUT (POT) and PARALLEL INPUT (PIN), permit any word in core memory to be presented in parallel at a connector; or, inversely, permit signals sent to a connector to be stored in any core memory location. The execution of a POT or PIN instruction causes a signal to be sent to the external device involved in the input/output operation. This signal notifies the device to send its data word as soon as it is operational. When the device becomes operational during a Read or PIN operation, it transmits a Ready signal to the central processor while at the same time presenting its data word. The computer places the received data word into a specified memory location without disturbing any arithmetic registers. The computer "hangs up" during the execution of PIN until it receives the Ready signal from the external device.

During the execution of a POT instruction, the central processor transmits a signal to the external device, alerting it to receive a data word. When the device becomes operational, it transmits a Ready signal to the central processor, which releases the data word to the external device. The computer "hangs up" during the execution of POT until it receives the Ready signal from the external device.

For special system requirements, POT and PIN can be used effectively with other instructions to produce high-speed, synchronized, data transfers between the central processor and external devices without the use of a communication channel. Selective input/output to and from these devices is accomplished by preceding POT or PIN with an EOM to alert the desired device by specific address. By preceding the POT or PIN with an SKS, the Ready signal of the special device can be tested after the execution of the EOM but prior to execution of the parallel transfer instruction; a possible computer "hang-up" can thereby be avoided. If the Ready signal from the external device sets one of the priority interrupts, parallel input/output operation can occur as soon as the external device is able to transmit or receive. Since the Ready signal initiating the interrupt is present through the POT or PIN execution, no computer "hang-up" occurs.

PARALLEL INPUT

PIN stores the contents of 24 input lines in parallel in the effective memory location.

POT transmits the contents of the effective memory location in parallel to 24 output lines of an external device.

Registers Affected: None
Timing: 3 + wait

## SINGLE-BIT INPUT/OUTPUT

Operating in the System mode, the two instructions, ENERGIZE OUTPUT M (EOM) and SKIP IF SIGNAL NOT SET (SKS), provide single-bit input/output transmissions.

Execution of a System Mode EOM causes a signal of approximately 1.4 microseconds to be transmitted to one of a possible 16,384 signal destinations. The System Mode EOM format is:

EOM ENERGIZE OUTPUT M

Bit position 3 through 8 contain the EOM instruction code, 02.

Bit positions 10 and 11 contain the System Mode indicator.

Bit positions 12 through 23 contain the 12 -bit address field that specifies the special system destinations.

Bit position 2 contains 0 .

Bit positions 0 and 1 are reserved for special system address bits.

Bit position 9 is reserved for use with the Data Multiplex System option.

Execution of a System Test Mode SKS causes a 14-bit address to be presented to the collection of special system devices. If the addressed external device is supplying a set signal to the central processor, the computer executes the next instruction in sequence from the SKS. If no signal is set, the computer skips the next instruction in sequence and executes the following instruction.
The SKS System Test format, which has each corresponding bit-set identical to the System EOM format, is:

## SKS SKIP IF SIGNAL NOT SET

## COMMUNICATION CHANNEL PROGRAMMING

## EXTENDED MODE

Programming a block transmission of data using the full facility of the input/output system includes these instructions: EOM (Alert), EOM (I/O Control), and POT (PARALLEL OUTPUT).

A sample sequence of instructions from a magnetic tape read operation follows. The octal configuration of each instruction is given.

| Location | Instruction | Comments |
| :---: | :---: | :---: |
| 1000 | 00242610 | This EOM specifies Channel W, bits 1 and 17 , (no 2 in O0, no 1 in O5) alerts the interlace, bit 9 (a 4 in O3) is in the Buffer Control mode (no 2 or 1 in O3) specifies forward direction of tape motion with no leader and BCD character format; bits 12, 13, 14, (a 4, no 2 and no 1 in O4) selects four characters per word assembly mode, bits 15, 16, (a 6 in O5) and connects the unit function address 10 to read tape number 0 . |
| 1001 | 00215001 | This EOM is in the Input/Output Control mode, selects the channel interrupt mode, bit 12,(a 4 in O4) disarms the End-of-Record interrupt, bit 13, (no 2 in O4) arms the Zero Count interrupt, bit 14, (a 1 in O4) selects terminal function 00, bits 15, 16, (no 4 or 2 in O5) and specifies high order word count of 01 (bits 20 through 23). |
| 1002 | 01301020 | This POT transmits to the channel the contents of location 1020. The location contains the word count and the starting location for data input. |
| 1020 | 00313500 | Bit positions 0 through 9 of this location contain the low order 10 bits of the word count. Bit positions 10 through 23 contain the 14 bits of the starting address |

The channel assembles the starting address from the EOM, bit 18, and from the word transmitted by the POT. In this sample, the starting address for the read operation is 135008. The word count is assembled from the same EOM, bits 19 through 23, and from the word transmitted by the POT. In this sample, the word count is 020068 . This is assembled as follows. Bits 19 through 23 of the EOM in location 1001 are 000 01; bits 0 through 9 of the transmitted word are 0000000110 . Assembling these bits into one 15-bit count, 000010000000110 , the word count becomes $0^{02006}{ }_{8}$.

These three instructions read one magnetic tape record of 2006word length into memory starting at location 13500. When the word count equals zero during the transmission, an interrupt is sent to Channel W interrupt level 31. Any further information
is ignored and when the tape reaches the End-of-Record, it is stopped, disconnected, and the channel becomes inactive.

## COMPATIBLE MODE

In the Compatible mode of channel operation, the second EOM may be omitted if the word count is less than 1023 (17778) words and the starting addresses are less than 16383 ( $37777_{8}$ ). The End-of-Word and End-of-Transmission interrupts are used when interrupts are desired. They can be armed/enabled or disarmed/disabled by the Enable/Disable instructions. Since the Extended input/output functions that are specified in the second EOM cannot be used, the latter two interrupts are used along with SKS tests to determine the terminal conditions of input/output transmissions. This I/O mode operates only for Channels W, Y, C, D.

A sample line print sequence programmed in the compatible mode follows:

| Location | Instruction Comments |  |
| :--- | :--- | :--- |
| 1000 | 00242660 | This EOM specifies Channel W, alerts the interlace, specifies four <br> characters per word, and connects the unit function address 60 for <br> Printer Number 1. |
| 1001 | 01301030 | This POT transmits to the channel the contents of location 1030. |
| 1030 | 02042000 | The location contains the word count and the starting address for <br> output. Bits 0 through 9 contain the word count of $41_{8}$; the start- <br> ing address is $2000_{8}$. |

Since the input/output facility is less comprehensive in this mode, the user should be aware of the terminal conditions that will occur. For output, the mode is equivalent to functions 00 and 01 ; that is, when C words have been transmitted, the output terminates, and when the last character has been sent, the device disconnects. If the interrupt system is enabled, an End-of-Transmission interrupt to location 33 occurs when the device disconnects. No interrupt occurs on level 31.

For input, this mode is equivalent to functions 00 and 01 if the End-of-Record is encountered before the word count is reduced to zero. If the word count is reduced to zero before the End-of-Record is encountered, the interlace portion of the channel disengages all control of the channel buffer. The buffer con-
tinues to assemble characters until a word is completed. If the interrupt system is enabled, the buffer then generates an End-of-Word interrupt on level 31 . The program has approximately 1.5 character times to reload the interlace if reading is to continue. On Channel W (or Y ) the contents of the buffer at this time can be stored with the WIM (YIM) instruction.

If this form (EOM, POT) is used with Channels $E$ through $H$, the Terminal Function mode is 00 with no interrupts armed.

This mode of channel operation should generally not be used on input unless the record length of the input records is fixed and known.

## CONTROL CONSOLE

The basic XDS 930 Computer System provides a console for operator control. This console connects directly to the central processor, contains switches for operation, and displays the contents of operational registers.

## DISPLAYS

The registers displayed on the console directly reflect the contents of the hardware registers. If the operator changes or clears a display, the contents of the actual register also change identically.

## PROGRAM LOCATION

The program counter is a 14 -bit register that contains the location of the next instruction to be executed. The programmer may change the counter by inserting a BRU into the Instruction Register and executing it. When the computer is in the IDLE state, this register displays the location of the instruction to be executed next.

## INPUT/OUTPUT

The UNIT lights contain the unit address of the peripheral device currently connected to the selected channel.

The ERROR light reflects the status of the channel error indicator. Setting the I/O DISPLAY SELECT thumbwheel switch selects the channel to be displayed.

## MEMORY EXTENSION

There are two memory extension indicators. The right one lights when EM3 does not contain three (3); the left one lights when EM2 does not contain two (2).

## HALT

The HALT light is on whenever the computer executes an HLT instruction while in the RUN position. To clear this indicator, set the RUN-IDLE-STEP switch to IDLE.

## OVERFLOW

This display shows the status of the Overflow Indicator.

## REGISTER DISPLAY

This display consists of 24 binary indicators with a clear button for the entire register and a set button for each indicator. The REGISTER thumbwheel switch selects the internal register whose contents are to be displayed. The selectable registers are:

C C Register, which contains the full instruction immediately prior to its execution

A A Register
B B Register
X Index Register X

To change the contents of the selected register, press the indicator button(s) in the corresponding bit positions. The computer must be in the IDLE state and the register previously cleared. Pressing a button places a l-bit into the selected position of the register.

## MEMORY PARITY

If an operand or instruction access from memory encounters a parity error, this light turns on. Setting the MEMORY PARITY switch to CONTINUE clears the indicator and turns off the light.

## INTERRUPT ENABLED

The INTERRUPT ENABLED light is on whenever the interrupt system is enabled.

## SWITCHES

## POWER

The POWER switch turns the computer system power on or off. When power is on, the switch is lit.

## FILL

The operator has the option of four input media to initially load or "fill" the computer. The pair of three-position, spring-loaded, center-return, toggle FILL switches are labeled: PAPER TAPE MAG TAPE and CARDS-DRUM. For example, to select and initiate filling from paper tape on Channel $W$, set the first toggle switch to PAPER TAPE and release.

The fill procedure is:
a) Set up the selected input device with the input program. The initial portion of the program contains the "bootstrap" (the short-load program).
b) Set the RUN-IDLE-STEP switch in the IDLE position.
c) Press the START switch.
d) Set the RUN-IDLE-STEP switch in the RUN position.
e) Press one of the four FILL switches. This will cause a WIM 2 (03200002) instruction to be inserted into the Instruction Register and will load the Index Register with 77777771 . Depending on which switch is pressed, activation of one of the following four devices on Channel W will occur:

Paper Tape Reader No. 1-Unit Address 04
Card Reader No. 1 - Unit Address 06
Disc File No. 1-Unit Address 26
Magnetic Tape Unit No. 0 - Unit Address 10 The FILL switch also prepares the channel to operate in the forward, binary, four characters per word mode.

A "bootstrap" program must be in position to be read as the first input from the device. A typical bootstrap program is:

Figure 4-3. XDS 930 Control Panel

| Location | Instruction | Address |
| :---: | :---: | :---: |
| 00002 | WIM | 00012, 2 |
| 00003 | BRX | 00002 |
| 00004 | LDX | 00011 |
| 00005 | WIM | 00000, 2 |
| 00006 | SKS | 21000 |
| 00007 | BRX | 00005 |
| 00010 | BRU | BEGIN |
| 00011 | OCT | Starting address with indirect address "tag" |

The WIM 00002 instruction that is forced into the Instruction Register stores the first word of the "bootstrap" program in location 2. The computer then executes the contents of location 2. The Index Register, which contains -7, modifies the WIM in 2. The effective address of the WIM is then 00003 so that the second word is stored in 3 . This word is a BRX back to the WIM.

These two instructions then load the remainder of the "bootstrap" program. The remaining six words can be those needed for the specific loading that is to be done. The one shown loads a record of any length. The Buffer Ready test in location 6 skips when the End-of-Record has been reached. In "bootstrapping" from paper tape or magnetic tape, the record may be of any length. From cards, the record is 40 words.

## RUN-IDLE-STEP Switch

This is a three-position, toggle switch with two stationary positions and a spring-loaded, momentary position in STEP. In the RUN position, computation occurs at machine speed. In the IDLE position, the computer idles immediately after an instruction has been read from memory. If the REGISTER switch is in the "C" position, the REGISTER DISPLAY shows the complete instruction. In the STEP position, the computer executes the instruction and returns to the Idle state. Release the switch to the IDLE position before performing another step.

## HOLD Switch

When the HOLD switch is on, the current contents of the program counter are held. Instructions inserted into the $C$ Register and executed do not step the program counter (i.e., it is inhibited from counting).

## START Switch

This switch initializes the control section of the computer. It resets all channels, clears the $\mathbf{P}$ Register, Overflow Indicator, Memory Parity Error Indicator, and sets up a HALT (00) instruction in the C Register. The RUN-IDLE-STEP switch must be in IDLE and the REGISTER SELECT switch must be at $C$ when pressing this switch. It clears all interrupts and disables the interrupt system. The EM3 register is set to 3 and the EM2 register is set to 2 .

## REGISTER Select Switch

This four-position, thumbwheel switch selects the register to be shown on the Register Display lights.

## I/O DISPLAY SELECT Switch

This eight-position, thumbwheel switch selects the channel from which the unit address and error indicator are displayed in the INPUT-OUTPUT lights.

INTERRUPT ENABLED Switch
If this switch is in the COMPUTER position, the Interrupt System may be enabled or disabled under program control. Placing the switch in the ENABLE position enables the Interrupt System regardless of program operations. The switch is stationary in the COMPUTER position and momentary in the ENABLE position.

## MEMORY PARITY Switch

If this switch is in the HALT position, the computer enters an Idle state whenever a memory parity error occurs. If this switch is in the CONTINUE position, the computer does not change state when memory parity occurs.

## BREAKPOINT Switches

The program may detect the status of these four switches by using a breakpoint test. The switches, labeled RESET and SET, control pre-determined options within the program.

## MEMORY CLEAR Switches

To clear first 16 K words of memory, press the START switch and then press both MEMORY CLEAR switches simultaneously. To clear from 16 K through 24 K , set the Extend Memory Registers $E M 2=4$ and $E M 3=5$, then press these two switches simultaneously. To clear from 24 K to 32 K , set EM2 $=6$ and $\mathrm{EM} 3=7$, then press both switches simultaneously.

## INPUT/OUTPUT TYPEWRITER

The control console contains an electric, input/output typewriter for operator control, error or status messages, and similar functions. The Typewriter is connected to Channel W, has the input unit address 01, and the output unit address 41. Appendix A-1 lists the typewriter codes.

The typewriter control instructions follow. These sample instructions use Typewriter Number 1 on Channel $W$ with four characters per word mode.

## RKB 0, 1, 4 READ KEYBOARD W1, 4 characters/word

00202601
This instruction alerts Channel W and connects Typewriter Number 1 to it. RKB prepares the channel to read input from the keyboard. It also lights the input indicator on the typewriter.

```
TYP 0, 1, 4 WRITE TYPEWRITER W1,
    4 characters/word
00202641
```

This instruction alerts Channel W and connects it to Typewriter Number 1. TYP prepares the channel to write output to the typewriter.

## PROGRAMMING EXAMPLES

These examples present a straightforward sample of reading and writing with the typewriter under program control.

## EXAMPLE: Typewriter Output

This routine causes the following message

## ASSEMBLY DONE ENTER NEW PROGRAM

to be typed out under program control. The computer stores the internal codes for these characters in memory beginning in location 2000. The routine inserts the carriage return code, 52 , and the space code, 12 , where needed and requests End-of-Record interrupt. It is written as a closed subroutine using interrupts, and uses Channel W and Typewriter Number 1.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1000 | PZE |  | This instruction is an assembler instruction, used here as a convenient way to reserve the entry location for subroutine use. |
|  | CLR |  | This clears the $A$ and $B$ Registers. |
|  | STA | SWICH | This clears the location called SWICH. SWICH later indicates to the main program that output is complete. |
|  | TYP | *0, 1, 4 | This instruction connects Typewriter Number 1 to Channel W for output, specifies four characters per word mode, and alerts Channel W interlace. The instruction is an EOM with octal configuration, 00242641. |
|  | EXU | WRITE | This instruction causes the Input/Output EOM in location WRITE to be executed. |
|  | POT | WRITE + 1 | This instruction sends the word count and starting address in WRITE +1 to the channel. |
|  | BRR | 1000 | This instruction branches back to the main program. |
| WRITE | $\begin{aligned} & \text { EOM } \\ & 00403720 \end{aligned}$ | 16200 | This EOM specifies terminal output function code 01 (IOSD) and the End-of-Record interrupt. The word in WRITE +1 specifies that eight words will output from memory beginning in location 2000. According to terminal function 01, when the word count equals zero during the transmission, the output terminates, and when the last character is out, the device disconnects; at this time, the interrupt occurs. |

The computer processes the main program while the channel performs the output operation. When finished with the output, an interrupt to interrupt level 33, the End-of-Record location for Channel W, occurs.

| BRM 33 | OKAY | This instruction, placed in location 33, branches and <br> marks to location OKAY elsewhere in memory. |
| :--- | :--- | :--- |
| OKAY | SZE | This instruction saves the entry location. |
| MIN | This instruction increments location SWICH as an indica- <br> tor for the main program. |  |
| *OKAY | This instruction branches to the main program and clears <br> the active interrupt. |  |

This is the internal code for the output message:

|  | A | S | S | E | M | B | L | Y | Sp | D | 0 | $N$ | E | $C / R$ | E | N |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2000 | 21 | 62 | 62 | 25 | 44 | 22 | 43 | 70 | 12 | 24 | 46 | 45 | 25 | 52 | 25 | 45 |
|  |  |  |  |  | N | E | W | Sp | P | R | $\bigcirc$ | G | R | A | M | Sp |
| 2004 |  |  |  |  | 45 | 25 | 66 | 12 | 47 | 51 | 46 | 27 | 51 | 21 | 44 | 12 |

EXAMPLE: Typewriter Input
The operator requests control to input four control characters. The subroutine is assumed to have been entered under program control. There is no request for terminal interrupts in this example.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| INPUT | PZE |  | This instruction saves the entry location. |
|  | RKB | *0, 1, 4 | This instruction connects Channel W to Typewriter Number 1, specifies the four characters per word mode, and alerts the interlace. The input request light is lit. The octal configuration of the instruction is 002 42601. The asterisk prefixed to the address of read and write controlling EOM instructions indicates the setting of the interlace alert bit (9). |
|  | EXU | CHARS | This instruction executes the instruction at location CHARS. |
|  | POT | CHARS + 1 | This instruction transmits to the channel the word count and starting address. |
|  | CAT | 0 | This instruction tests for channel not active. If the channel is active when the computer executes CAT, it executes the next instruction in sequence. If the channel is inactive, the computer skips the next instruction and executes the following one. |
|  | BRU | \$-1 | This instruction branches to the CAT instruction. The dollar sign and accompanying signed integer in the address field is an assembler declaration for the indicated number of locations prior to or following the current one. Plus indicates following. |
|  | BRU | CHECK | This instruction branches to an assumed routine to determine what characters were typed in. |
| CHARS | $\begin{aligned} & \text { EOM } \\ & 00047640 \end{aligned}$ | 14200 | This EOM specifies terminal input function 01 and no interrupt at the end of transmission. The word in CHARS +1 specifies that one word can be input into locat:on 4000. Only one word is accepted before the channel disconnects and goes inactive. The Count Equals Zero causes channel disconnect. |

## PERIPHERAL EQUIPMENT DESCRIPTION

Communication channels facilitate a wide range of input/output operations. Combinations of input/output functions can perform Scatter-Read and Gather-Write operations. A channel may read many records into one contiguous area of memory, or skip portions of records and read subsequent portions.

This section describes some of the input/output devices, available in the computer system and explains their use.

## PAPER TAPE INPUT/OUTPUT

## Format

Paper tape used with the computer is one-inch wide, affording space for eight data holes and a sprocket hole in each frame of information. There are ten frames per inch of paper tape. Six hole positions contain information, one contains the odd parity check, and the eighth is unused.

The organization of information on the tape is in blocks. A block is a group of frames set off by a gap of at least one blank frame (in which only the sprocket hole is punched) at either end. Blocks may be of variable lengths.

For some operations a tape may consist of only one block, such as a source language tape prepared off-line. In this case, the program need not read the entire block at one time, but may stop the reader between frames, and then start again to read the remainder or another portion of the block.

## Reading

All channel functions may be used in reading paper tape. An input/output function that terminates because of a zero count stops the tape between frames. A subsequent paper tape "read" starts the reader and allows the next frame to be read. An input/output function that terminates because of gap (End-ofRecord) stops the tape after the first blank frame of the gap. When the tape starts, the tape reader ignores any leading blank frames. After reading information from the tape, the reader recognizes a blank frame as gap and signals the channel with an End-of-Record indication.

Punching
When a channel addresses the paper tape punch, the punch motor also starts (if not already on). If the punch instruction so indicates, the punch unit punches a segment of leader (gap, or blank frames). Bit position 13 of a Channel EOM or EOD instruction, which addresses the punch, contains a " 0 " to punch leader; bit position 13 contains a " 1 " to punch without leader.

This instruction

$$
\text { PPT 0, 1, } 1
$$

00202044
prepares the punch on Channel $W$ to punch without leader. It sets the channel to operate with one character per word.

This instruction

$$
\text { PTL 0, 1, } 4
$$

00200644
prepares the punch and produces about 12 frames of leader. It sets the channel to operate with four characters per word.

No channel terminal function produces End-of-Record gap after punching a block. The EOM instruction that addresses the punch can only generate gap.

The punch operates at 60 characters per second, asynchronously. If the channel does not supply characters to the punch fast enough for operation at 60 cps , the punch waits for each character, losing no data and making no errors.

## Programming

There are no status tests for the Paper Tape Reader or Punch, that is, they are always ready for operation. When a channel addresses either device, the device starts to send or accept data within approximately one character time. The reader and punch operate only in the binary mode and the forward direction; they ignore any different mode specified, and use the forward-binary mode. Unit addresses of 04 and 05 are for Paper Tape Readers 1 and 2, respectively, and unit addresses 44 and 45 are for Paper Tape Punches 1 and 2.

## Paper Tape Instructions

The following instructions use Channel W, Paper Tape Number 1, with four characters per word format.

RPT 0, 1, 4 READ PAPER TAPE
00202604
RPT initiates a paper tape read operation on tape read station number 1 connected to Channel $W$ in the four characters per word format.

PTL 0, 1, 4 PUNCH PAPER TAPE WITH LEADER 00200644
PTL initiates a paper tape punch operation on tape punch station number 1 connected to Channel $W$ in the four characters per word mode. It generates approximately twelve frames of leader preceding the first punched frame.

PPT 0, 1, 4 PUNCH PAPER TAPE WITH NO LEADER 00202644
PPT initiates a paper tape punch operation on tape punch station number 1 connected to Channel $W$ in the four characters per word format. It generates no leader preceding the first punched frame.

The desired EOM, POT combination follows each of these instructions to control the input/output of data.

## EXAMPLE: Punch Paper Tape

This program punches one block of 20 words beginning in location 2000. A twelve-frame leader precedes the block. The routine is a closed subroutine that uses interrupts.
Location Instruction $\quad$ Address Comments

| 1000 | PZE |  | This instruction saves a place for the entry location. |
| :---: | :---: | :---: | :---: |
|  | CLR |  | This instruction clears the $A$ and $B$ Registers. |
|  | STA | WHERE | This instruction clears a switch location used as an indicator to the main program for completion of the punch operation. |
|  | PTL | *0, 1, 4 | This instruction connects Channel W to Paper Tape Punch Number 1, specifies four characters per word mode, and alerts the interlace. The instruction specifies leader to be punched, and if not already on, turns the punch motor on. The octal configuration of this EOM is 00240644. |
|  | EXU | PUN20 | This instruction executes the $1 / O$ Control EOM that sets the interrupt and selects output function 00. |
|  | POT | PUN20 + 1 | This instruction transmits to the channel the word count and starting address of the transmission. |
|  | BRR | 1000 | This instruction branches back to the main program. |
| PUN20 | $\begin{aligned} & \text { EOM } \\ & 01202000 \end{aligned}$ | 16000 | The EOM specifies terminal output function 00 (IORD) and the End-of-Record interrupt. The word in PUN20 1 specifies 20 words of output from memory to the punch beginning at location 2000 ( 0120 is 0248 shifted right one place; it is merged with 02000 to make the "POTted" control word). According to terminal output function 00 , when the word count equals zero during the transmission, the output terminates. The last word has not been fully transmitted at this time. When it is and the output is complete, the channel disconnects and the interrupt occurs. |

When the Count Equals Zero interrupt occurs:

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 33 | BRM | END | This instruction branches and marks to END. |
| END | PZE |  | This instruction saves a place for the entry location. |
|  | MIN | WHERE | This instruction increments WHERE as a flag. |
|  | BRU | * END | This instruction returns to the main program and clears the interrupt level. |

## EXAMPLE: Read Paper Tape

This program reads a block of 64 characters from paper tape. The routine uses the four characters per word mode, making the input 16 words. It turns the tape station on and requests a Count Equals Zero interrupt, level 31, for the operation on Channel W. The routine is a closed subroutine.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1000 | PZE |  | This instruction saves a place for the entry location. |
|  | CLR |  | This instruction clears the $A$ and $B$ Registers. |
|  | STA | SWICH | This instruction clears location SWICH used as an inputfinished indicator. |
|  | RPT | * 0, 1, 4 | This instruction connects Paper Tape Reader Number 1 to Channel W, specifies the four characters per word mode, and alerts the interlace. The octal configuration of this EOM instruction is 00242604. |
|  | EXU | REED | This instruction executes the EOM at location REED. |
|  | POT | REED + 1 | This instruction transmits to the channel the word count and starting address. |
|  | BRR | 1000 | This instruction branches back to the main program for processing while the input operation is in progress. |
| REED | $\begin{aligned} & \text { EOM } \\ & 01003720 \end{aligned}$ | 15200 | This EOM specifies terminal input function 01 (IOSD) and the Count Equals Zero interrupt. The word in REED +1 specifies that input into memory begins in location 2000 and that 16 words will be read before the operation terminates. When the word count equals zero, the interrupt occurs. Then the channel disconnects. When the tape read operation is complete, the Count Equals Zero interrupt occurs at level 31. |
| 31 | BRM | FNISH | This instruction, in location 31 for this example, branches and marks to location FNISH. |
| FNISH | PZE |  | This instruction saves the entry location. |
|  | MIN | SWICH | This instruction sets an input-finished switch for use by the main program. |
|  | BRU | *FNISH | This instruction branches back to the main program and clears interrupt level 31 from the active state. |

The programmer can make a test to the channel, CET, for parity error during the read operation before the BRU instruction.

## CARD INPUT/OUTPUT

## Format

The computer uses 80 -column cards in two formats. The card reader reads Hollerith-coded information from cards and transmits the corresponding XDS character codes to memory. In this mode, each column contains the equivalent of one 6-bit internal character. Appendix A-1 lists the character codes.

The card reader reads binary-coded information from the card with two 6-bit characters per column. In binary mode, two columns form a word. The top six rows (12-3) of column 1, for example, form the first character and the bottom six (4-9) the next character. The reader reads from column 1 to 80 in this top-bottom order. A single card holds 160 characters or 40 binary words.

Figure 4-4 shows the relation of Hollerith information on a card and in memory. Hollerith output to the punch is identically the reverse.

Reading
The card reader scans the card, column by column, starting with column one, and transmits either 80 or 160 characters to the channel depending on the mode of operation. When power is on and cards are in the hopper, the operator makes the card ready by pressing the START button. During program operation, the program must test for the ready condition before initiating a card read operation. Once an EOM instruction starts the card read, the desired channel function (EOM, POT) may control the flow of information into memory. In the Hollerith mode, any column read that is not punched in one of the 64 combinations listed in Appendix A-1 results in a Validity check. The presence of a Validity check causes an error signal to be sent to the channel and lights the VALIDITY CHECK light on the reader.

If the stacker should become full, or the hopper empty, the reader is not ready and the NOT READY indicator lights. The card reader remains in the NOT READY state until the operator corrects the situation and presses the START button. Upon reading the last card, the reader sets an End-of-File signal if the EOF ON switch is on. The central processor can test the End-of-File condition to determine if more cards are in the hopper.

Card A

Figure 4-4. Card Read Into Memory in Hollerith

Punching
The card punch punches cardsarow at a time, starting with row 12. The punch coupler, in both the Hollerith and binary modes, automatically rearranges the information to be punched. The card punch program must present the entire card image, 80 or 160 characters, to the punch 12 times for each card. This is necessary because of the way the punch operates. Aseach row of the card approaches the punch station, the coupler examines every character of the image to determine which column positions in that row should be punched. After the 12th output, the card punch punches row 9 and completes the card cycle.

The card punch is Ready to punch if there are cards in the magazine, the stacker is not full, and the operator has pressed the START button. The punch remains Ready as long as the above conditions are true. A Punch Card instruction given when the punch is Ready causes a card to feed past the punch station. The program must then address the punch and give the same instructions 12 times to transmit the card image to the coupler.

## Programming Instructions

The Card Reader and Punch instructions follow. They use unit number 1 on Channel $W$ with the four characters per word transmission mode.

## Card Read Instructions

## CRT 0, 1 CARD READER READY TEST

04012006
This test determines if the selected card reader is Ready to read. If so, the computer skips the next instruction in sequence and executes the following instruction. If the reader is Not Ready, the computer executes the next instruction in sequence.

## FCT 0, 1 FIRST COLUMN TEST

04014006
This test determines if the first column is about to be read by the card reader. Since the time elapsing between the execution of a card reader EOM and the reading of the first column is approximately 85 milliseconds ( 48,450 computer cycles), this test allows the computer to perform other operations during thistime. If FCT is executed less than 1.2 milliseconds (approximately 685 computer cycles) before the first column is due to be read, the computer skips the next instruction in sequence and executes the following instruction. If FCT is executed 1.2 milliseconds (or more) before the first column is due to be read, the computer executes the next instruction in sequence (does not skip).

## CFT 0, 1 CARD READER END-OF-FILE TEST 04011006

This test determines if the End-of-File condition from the card reader has been detected. If not, the computer skips the next instruction in sequence and executes the following instruction. If the EOF condition has been detected, the computer executes the next instruction in sequence.

The reader remains in the End-of-File condition until the operator adds cards to the hopper or turns off the EOF ON switch.

RCD 0, 1, 4 READ CARD DECIMAL (Hollerith)
00202606
RCD alerts the card reader, causes a card to feed from the hopper, and selects the Hollerith mode (as each column is read it is translated to an XDS internal code). This mode can read up to 80 characters ( 20 words) from a card.

RCB 0, 1, 4 READ CARD BINARY
00203606
RCB alerts the card reader, causes a card to feed from the hopper and selects the binary mode (as each column is read it is transmitted as two 6-bit binary characters). This mode can read up to 160 characters ( 40 words) from a card.

SRC 0, 1 SKIP REMAINDER OF CARD 00212006
This instruction causes the reader to stop transmission of characters to the channel. The remaining characters are not checked for validity, but a read check, feed check, or end-of-record condition will cause an End-of-Record interrupt and disconnect the card reader from the channel.

## Card Punch Instructions

PBT 0, 1 PUNCH BUFFER TEST
04012046
This instruction is used to test the status of the punch buffer. If the punch buffer is clear (empty) and ready for loading when PBT is executed, the computer skips the next instruction in sequence and executes the following instruction. If the punch buffer is not clear when PBT is executed, the computer executes the next instruction in sequence (does not skip). The punch buffer is always clear if the punch is ready to feed and punch.

CPT 0, 1 CARD PUNCH READY TEST 04014046
This test determines if the selected card punch is Ready to punch. If so, the computer skips the next instruction in sequence and executes the following instruction. If the punch is Not Ready, the computer executes the next instruction in sequence.

Before the punch is Ready, the operator must place blank cards in the magazine and press the START button.

PCD 0, 1, 4 PUNCH CARD DECIMAL (Hollerith) 00202646
PCD alerts the punch, causes a card to feed past the punch station, and selects the Hollerith mode. A transmission of 80 characters ( 20 words) must follow this instruction. The instruction PCD followed by the transmission instructions for 80 characters per card is repeated 12 times.

PCB 0, 1, 4 PUNCH CARD BINARY
00203646
PCB alerts the punch, causes a card ta feed past the punch station, and selects the binary mode. A transmission of 160 characters ( 40 words) must follow this instruction. The instruction PCB followed by the transmission instructions for 160 characters per card is repeated 12 times.

This program reads one card in Hollerith mode. It is a closed subroutine that uses interrupts; assume the interrupt system is enabled.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1000 | PZE |  | This is an assembler instruction. It conveniently reserves a location for the subroutine entry. |
|  | CRT | 0, 1 | This instruction is the card reader Ready test for Card Reader Number 1 on Channel W. |
|  |  |  | If Not Ready, the computer executes the next instruction. If Ready, the computer skips the next one and executes the following instruction. The octal configuration is 04012006. |
|  | BRU | \$-1 | This instruction branches back to the test on Not Ready. The programmer can put an exit to a Not-Ready corrective routine here. |
|  | RCD | * 0, 1, 4 | This instruction connects Card Reader 1 to Channel W, alerts the interlace, starts a card moving toward the read station, and specifies Hollerith mode. The octal configuration for this instruction is 00242606. |
|  | EXU | READ | This instruction executes the I/O Control EOM at location READ. |
|  | POT | READ + 1 | This instruction transmits to the channel the word count and starting address. |
|  | BRR | 1000 | This instruction branches back to the main program. |
| READ | $\begin{aligned} & \text { EOM } \\ & 01203720 \end{aligned}$ | 15200 | This EOM specifies terminal input function 01 (IOSD) and the Count Equals Zero interrupt. The word in READ +1 specifies that a record will be read into memory beginning at location 2000 and specifies a 20 -word limit. |

The computer processes the main program while the channel performs the card read operation. When finished with the input, transmission of an interrupt will occur to the interrupt level 31, the Count Equals Zero location for Channel W.

| 31 | BRM | TEST | This instruction, placed in location 31 for this example, branches and marks to location TEST. |
| :---: | :---: | :---: | :---: |
| TEST | PZE |  | This instruction saves a location for the routine entry. |
|  | CET | 0 | This instruction tests for an error on Channel W. Its octal configuration is 04011000 . |
|  | BRM | ERR | The computer executes this instruction if there is an error on Channel W. Assume that ERR is the entry to a corrective subroutine. |
|  | BRU | * TEST | This instruction returns control to the main program and clears interrupt level 31. The computer executes this instruction if no error is detected. |

This program punches one card in Hollerith mode. It is a closed subroutine that uses interrupts. The Index Register counts the 12 times the program presents the card image to the punch.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1000 | PZE |  | Saves the location for the subroutine entry. |
|  | CLR |  | Clears the $A$ and $B$ Registers. |
|  | STA | SWICH | Clears a switch for later use. |
|  | $\begin{aligned} & \text { LDA } \\ & \text { STA } \end{aligned}$ | $\begin{aligned} & 1000 \\ & \text { ENTR2 } \end{aligned}$ | This pair of LDA and STA place the main program mark address in location ENTR2. |
|  | MIN | ENTR2 | MIN adds one to the stored contents. |
| MCRDS | LDX | ROWS | Initializes the Index Register with 00077765 (octal), which is -11 decimal. |
|  | CPT | 0, 1 | Tests the card punch for a Ready condition. The card punch is Number I on Channel W. |
|  | BRU | \$-1 | The computer executes this instruction if the punch is Not Ready. It branches back to the test, CPT 0, 1. The programmer can place an exit to a time loop here with the facility to tell the operator that the card punch will not become Ready. |
| GETRW | PCD | * 0, 1, 4 | The computer executes this instruction if the punch is Ready. It alerts Channel W with interlace, connects Card Punch Number 1 to Channel W, starts a card moving toward the punch station, and specifies four characters per word and Hollerith mode. |
|  | EXU | PNCH | Executes the EOM located in PNCH. |
|  | POT | $\mathrm{PNCH}+1$ | Transmits to the channel the word count and starting address. |
|  | BRU | ENTR2 | Branches back to the main program. |
| PNCH | $\begin{aligned} & \text { EOM } \\ & 01203720 \end{aligned}$ | 16000 | This EOM specifies terminal output function 00 (IORD) and the End-of Record interrupt. The word in PNCH +1 specifies that 20 words will be output from memory beginning in location 2000. |
| ROWS | 00077765 |  | Note that the program must send the card image to the channel twelve times to punch a card. |

The computer processes the main program while the channel performs the output. When finished with the output, transmission of an interrupt will occur to the interrupt level 33, the End-of-Record location for Channel W.

| BRM | ENTR2 |  |
| :--- | :--- | :--- |
| ENTR2 | BRE | Saves a location for routine entry. |
| GETRW | Increments the index by one. If the base has not been incremented <br> through zero, the next instruction executed is at location GETRW. <br> When the base increments to zero, the computer executes the next in- <br> struction in sequence. The Index counts row times on the card. |  |

MIN SWICH Sets a switch to indicate to the main program that the punch operation is complete.

BRU *ENTR2 Returns control to the main program and clears the interrupt.

## MAGNETIC TAPE INPUT/OUTPUT

## Format

Magnetic tape units used in XDS computer systems are IBM-compatible. The tape is one-half inch wide, Mylar base material, 1.5 mils thick. Tape reels ( $10 \mathrm{l} / 2$-inch, plastic) contain up to 2400 feet of tape. A reflective marker, placed on the back of the tape approximately ten feet from the beginning of it, indicates the load point. The leading ten feet leave space for threading tape through the guides on the unit. The load point marker is on the Mylar side of the tape along the edge nearest the operator when the tape is mounted. A similar marker is along the other edge of the tape to mark the end-of-reel. About 14 feet of tape are reserved between the End-of-Reel marker and the end of the tape. This space includes at least ten feet of leader and enough tape to hold a record of 9,600 characters in 200 bpi density after sensing of the End-of-Reel marker.

Character recording on tape is in seven parallel tracks. A change in the magnetic flux in a track records a l-bit for a given character position. No change in magnetic flux indicates a 0 -bit. Six of the tracks are for information; the seventh track is a parity check. The system allows both even and odd parity, as needed. Binary recording uses odd parity. In this mode, the tape unit records the six-bit characters from the channel without change. Binary-coded decimal (BCD) recording uses even parity. In this mode, the tape control unit transforms characters from the channel to conform to standard IBM, $B C D$ interchange code (see Appendix A-1).

Arrangement of information on tape is in blocks that moy contain one or more records. Only the capacity of available core storage in the computer limits block length. An inter-record gap (section of blank tape) about $3 / 4$-inch long separates blocks of records on tape. In writing, the tape unit automatically produces gap at the end of a record or block. Reading begins with the first character sensed after the gap and continues until encountering the next gap.

An inter-record gap, followed by a special, single-character record, marks the end of a file of information. The character is a Tape Mark (0001111). Writing a one-word record in BCD with one-character-per-word format can record such a mark. A reel of tape may contain one or more files. On reading an End-of-File record, the tape control unit stops the tape and sets its End-of-File indicator, which the program may test.
The tape control unit considers any record that contains only Tape Mark ( 0001111 ) characters an End-of-File. The tape unit reads such characters into memory like any other characters.

As the tape unit writes information it makes an odd-even count of the number of 1 -bits in each track. At the end of each record it writes a bit for each track such that the total number of l-bits in each track is even. This parity check sum is always even whether the character parity is even or odd. The character containing these check bits is the longitudinal parity character; the tape unit writes it slightly past the end of recorded information in the block.
The longitudinal check character always reflects an even parity check for each channel. In the BCD mode, the check character itself always has an even number of 1 -bits. In the binary mode, however, the check character may have either an even or an odd number of 1 -bits. This means that a reverse scan over a binary record may result in turning on the error indicator
in the channel even though the record is correct. As a general rule, the program ignores the error indicator after a reverse operation.

It is possible to write tape in a 1-, 2-, or 3-character-perword mode provided that the rate of characters is sufficient. On reading, however, the tape unit uses the character count to ascertain when it has read two characters and can look for gap. If a l-character-per-word "read" is in operation, a single noise character will stop the tape. In reverse scan a l-charac-ter-per-word operation causes the tape to stop after detecting the longitudinal check character at the end of the record. This means that the tape stops in the recorded information.

All scan operations must be in 3- or 4-character-per-word mode or the tape does not stop when it reaches gap.

As a general rule, the user should program tape units for three or four characters per word, if possible. The write-tape-mark operation is an exception to this rule.

Use of the TAPE READY TEST (TRT) between tape operations of opposite direction ensures that the tape unit stops and reverses. It is an advisable programming practice to terminate tape writing by several inches of erasure whenever subsequent resumption of recording is anticipated. This eliminates the effects of a possible extraneous character that might arise through subsequent tape repositioning.

## Reading

Once a tape starts with a Read Binary or Read BCD EOM or EOD, it continues until the tape unit detects an End-of-Record gap. If the computer does not instruct the tape unit to continue, it stops in the middle of that gap. When the tape stops, the tape unit disconnects from the channel. If the tape encounters an End-of-File, the tape control unit sets its EOF indicator. The central processor can test this indicator, which remains set until the tape unit control receives a new EOM/EOD on that channel. The tape always stops after the Tape Mark.

At the end of the file the program reads the EOF character (0001111) into memory along with its check character. In a four-character-per-word "read", this appears in the first word of the input area as a 17170000 word.

When the tape unit is writing on tape, it may transmit flux disturbing surges ahead of the current writing positions; these surges affect previously written records further down the tape. This means that a record in the middle of a file cannot be updated or rewritten if the records that follow it are to be read.

Any errors detected either by the channel in the character parity check or by the control unit with longitudinal parity check sets the error indicator in the channel. When detecting such an error in reading, the routine should backspace the tape over the erroneous record and attempt to reread the record.

The tape unit backspaces over records using the Scan feature. A Scan reverse EOM or EOD starts the tape in reverse. The program then waits for the channel to become ready or waits for the End-of-Transmission (if enabled). When the buffer becomes ready or the End-of-Transmission interrupt occurs, the
tape stops in front of the backwardly traversed record. If the program hs enabled the interrupts, the End-of-Word (II) interrupt occurs prior to the End-of-Transmission interrupt; executing a WIM to a dummy location and clearing the interrupt with a BRU indirect ignore the interrupt.

A Scan operation is similar to a Read operation except that the channel shifts the characters read through its Word Assembly Register, but does not consider a word complete until it encounters a tape gap. When the tape reaches the gap, the channel uses the last four characters in the word assembly as the only word read from the record. When scanning in reverse, the word consists of the last four characters scanned, which are the first four logical characters of the record. This opera- tion assembles these characters in reverse. For example, if the first four characters of the record are 1234 and the tape is scanning the record in reverse, these appear as 4321 in the word stored for that record.

The same operation occurs in the forward scan with the last four characters of the record forming the word stored. The Scan is useful for reverse searching on the first word of the records in the file being searched. In this case, the routine starts the tape in a reverse scan and loads the channel interlace with a terminal function 10 with a word count of 1 and arms the Count Equals Zero interrupt. When the tape reaches the beginning of the record, the channel stores the first word and interrupts the program which checks the key word against a search key. If they agree, then the program need only wait for the channel to become inactive (ready) and the routine reads the record forward. If the record is not the desired one, the program gives another "scan reverse" without waiting for the channel to become inactive, and reloads the channel interlace to scan the next record.
If the tape encounters the End-of-Reel marker while reading, the tape logic sets the End-of-Reel indicator in the tape unit; the program can test this at any time. An End-of-File normally indicates the end of recorded information on tape. It is possible, however, to use the End-of-Reel indicator to mark the last record on the reel.

## Writing

Once a tape unit is ready and the file-protect ring is on the tape reel, that is, the file-protect test is false, a Write operation can begin. The write tape EOM starts tape motion; the tape remains in motion until it receives the termination signal from the buffer. The tape control unit then writes the remaining characters of the record and writes the longitudinal check character. When the read-after-write head reads this check character, the tape signals the channel it has reached gap. If the unit receives no further write instruction within one millisecond, the tape stops and disconnects.

If the user wishes to backspace or rewind and then to return at some later time to record additional information at the end of the previous series of records, the routine should write an End-of-File character or erase a segment of tape after the series of written records. This practice provides positive identification of the end of a record and facilitates return to a specific location on the tape. If the programmer does not use this method, the tape may not subsequently stop in the same location at the end of the series of records as it did when writing the last record. This would leave a segment of tape in the gap which has not been writien and may cause erroneous operation when reading the tape.

In addition to writing under program control, the program can also erase magnetic tape. When using an erase EOM with an erase unit address, the tape unit operates as though it were in a Write mode, except that it records no information. The program or interlace supplies the count of the number of words to be erased.

This type of erase is useful for the correction of a write error. When a write error occurs, an ERASE TAPE REVERSE (ERT) starts the tape in reverse. The same count, used to write the record originally, controls the erase. This procedure ensures that the tape always returns to the beginning of the erroneous record, even if a bad spot on the tape might appear as a gap. The routine may now rewrite the record. If the Write still produces an error, the routine erases the record backward and then erases it foward, using the same count, and by-passes the section of tape where the difficulty occurred. The routine may now rewrite the record on a new section of tape.
The erase procedure can produce the required 3.75 inches of blank tape between the load point and the first record. This is done by erasing 150 words at 200 bpi density, 417 words at 556 bpi density, or 600 words at 800 bpi density.

Use of a one-character-per-word, BCD, Write instruction writes an End-of-File record. Then the program loads the channel interlace with a count of 1 and loads the address of a word containing the Tape Mark character (17) in the left-most position. EOM or EOD instructions to the tape units specify start-without-leader since the tape unit automatically generates gap at the end of all records for leader. A magnetic tape program should never include a leader instruction because an attempt to generate leader may cause an erroneous operation.

## Programming

The SKS and EOM instructions for normal tape operations follow. EOM instructions use four character per word format for units on Channel W.

## TRT $0, \mathrm{n}$ TAPE READY TEST

$040104 \ln$
TRT 0 tests tape unit number n on Channel W for Not Ready. If the tape is Not Ready, it skips the next instruction in sequence and executes the following instruction. If the tape is Ready, it executes the next instruction in sequence.
A tape is Not Ready if: (1) there is no physical unit set to the logical unit number being tested, (2) the selected unit is not in the Automatic mode, or (3) the tape is in motion for any operation.

FPT 0, n
FILE PROTECT TEST
$0401401 n$
Tests tape unit number $n$ on Channel $W$ for file protect. If the file-protect ring is present, the computer skips the next instruction in sequence and executes the following instruction. If not inserted, it executes the next instruction in sequence. The skip does not occur if there is no logical unit $n$ on the channel.

## BTT 0,n BEGINNING OF TAPE TEST

040 1201n
Tests tape unit number $n$ on Channel $W$ for the beginning of the tape. If not positioned on the load point marker, the computer skips the next instruction in sequence and executes the following instruction. If positioned on the load point marker, it executes the next instruction in sequence. The skip does not occur if there is no logical unitn on the channel.

Tests whether tape unit number $n$ on Channel $W$ is not positioned at the end of the tape. If the tape unit has not sensed the End-of-Reel marker, the computer skips the next instruction in sequence and executes the following instruction. If the End-ofReel marker has been sensed, it executes the next instruction in sequence. The End-of-Reel condition is reset when the tape unit moves the tape backward over the End-of-Reel marker. The skip does not occur if there is no logical unit $n$ on the channel.

DT2 0,n DENSITY TEST, 200 BPI
$0401621 n$

Tests tape unit number $n$ on Channel $W$ for being set at 200 bpi density. If not, the computer skips the next instruction in sequence and executes the following instruction. If so, it executes the next instruction in sequence.

DT50,n DENSITY TEST, 556 BPI 0401661 n

Tests tape unit number $n$ on Channel $W$ for being set at 556 bpi density. If not, the computer skips the next instruction in sequence and executes the following instruction. If so, it executes the next instruction in sequence.

DT8 0, n DENSITY TEST, 800 BPI 0401721 n
Tests tape unit number $n$ on Channel $W$ for being set at 800 bpi density. If not, the computer skips the next instruction in sequence and executes the following instruction. If so, it executes the next instruction in sequence.

TFT 0
TAPE END-OF-FILE TEST
04013610
Tests whether a tape under control of the tape control unit on Channel W encountered an End-of-File during the last Read or Scan operation. If not, the computer skips the next instruction in sequence and executes the following instruction. If so, it executes the next instruction in sequence.

The End-of-File indicator remains set until the program calls for another tape operation.

TGT 0
TAPE GAP TEST
04012610
Tests whether a tape unit on Channel $W$ has encountered gap since it received the last EOM/EOD instruction. If not, the computer will skip the next instruction in sequence and execute the following instruction. If so, it executes the next instruction in sequence. TGT will execute the next instruction during the approximately 0.75 millisecond that the tape-gap indicator is "true".

## MAGPAK TEST

0401021 n
Tape unit $n$ is tested for being a MAGPAK. If the tape unit is not a MAGPAK, the computer skips the next instruction in sequence and executes the following instruction. If the tape unit is a MAGPAK, the computer executes the next instruction in sequence.

WTB 0, n, 4 WRITE TAPE IN BINARY $0020365 n$
Starts tape unit $n$ on Channel $W$ in a Binary Write mode.

WTD 0, n, 4 WRITE TAPE IN DECIMAL (BCD) $0020265 n$

Starts tape unit $n$ on Channel $W$ in a BCD Write mode.

EFT $0, n, 4$ ERASE TAPE FORWARD 0020367 n
Starts tape unit $n$ on Channel $W$ in an Erase mode.

ERT 0,n,4 ERASE TAPE IN REVERSE $0020767 n$
Starts tape unit $n$ on Channel $W$ in reverse in an Erase mode.
'RTB 0, n, 4 READ TAPE IN BINARY 0020361 n

Starts tape unit $n$ on Channel $W$ in a Binary Read mode.

RTD 0, n, 4 READ TAPE IN DECIMAL (BCD) 0020261 n
Starts tape unit $n$ on Channel $W$ in a BCD Read mode.

SFB 0, n, 4 SCAN FORWARD IN BINARY $0020363 n$
Starts tape unit $n$ on Channel $W$ forward in a Binary Scan mode.

SFD 0, n, 4 SCAN FORWARD IN DECIMAL (BCD) 002 0263n
Starts tape unit $n$ on Channel $W$ forward in a BCD Scan mode.

SRB 0, n, 4 SCAN REVERSE IN BINARY $0020763 n$
Starts tape unit $n$ on Channel $W$ in reverse in a Binary Scan mode.

SRD $0, n, 4$ SCAN REVERSE IN DECIMAL (BCD) $0020663 n$
Starts tape unit $n$ on Channel $W$ in reverse in a BCD Scan mode.

REW 0,n REWIND 0021401 n
Starts tape unit $n$ on Channel $W$ in a Rewind. REW does not use the channel.

RTS 0 CONVERT READ TO SCAN 00214000

The tape unit currently in a read mode on the channel is instructed to convert from the read mode of operation to the scan mode of operation.

SRR $0 \quad$ SKIP REMAINDER OF RECORD ${ }^{\dagger} \quad 00213610$
The tape unit currently on the channel is instructed to skip the remainder of the record being read.

[^0]
## MAGNETIC TAPE EXAMPLE PROGRAMS

The following examples show samples of complete input/output programs for magnetic tape.

## EXAMPLE: Magnetic Tape Read

This program reads one record from Magnetic Tape Number 1 on Channel W. It uses the End-of-Record interrupt. The tape is not at its beginning or end.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1000 | PZE |  | Saves a location for the subroutine entry. |
|  | TRT | 0,1 | Tests Ready Magnetic Tape 1 on Channel W. If Magnetic Tape 1 is ready to perform an input/output operation, the computer executes the next instruction in sequence. If not, it skips the next instruction and executes the following one. The octal configuration is 04010411 . |
|  | BRU | \$+2 | Skips one instruction. |
|  | BRU | \$-2 | Branches back to TRT 0,1 . The programmer can place here an exit to a routine that determines reasons for the NonReady condition. |
|  | RTD | *0, 1,4 | Addresses Channel W, alerts the interlace, connects it to Magnetic Tape 1, specifies four characters per word and BCD modes, and starts tape motion. |
|  | EXU | REDTP | Executes the EOM located in location REDTP. |
|  | POT | REDTP +1 | Transmits to the channel the word count and starting address. |
|  | BRR | 1000 | Branches back to the main program. |
| REDTP | $\begin{aligned} & \text { EOM } \\ & 06203720 \end{aligned}$ | 16000 | This EOM specifies terminal input function 00 (IORD) and the End-of-Record interrupt. The word in REDTP +1 specifies that one record or 100 words, whichever is smaller, will be read into memory beginning in location 2000. Any remaining words in the record after the first 100 will be ignored. ( 0620 is equal to $1448_{8}$ shifted right one place; it is merged with 03720 to generate the "POTted" word.) |

The main program continues while the channel performs the input operation. When finished, the End-of-Record interrupt goes to location 33.

| BRM 33 | COMPL | This instruction in interrupt location 33 branches and marks <br> to COMPL to finish the read operation. |
| :--- | :--- | :--- |
| Saves a location for the routine entry. |  |  |

## EXAMPLE: Gather-Write Magnetic Tape

The program writes one record on magnetic tape. The gathering of the data written in that record is from three non-contiguous areas of memory. This program is a closed subroutine that uses the Count Equals Zero interrupt; it uses Channel W and Magnetic Tape Number 1 on Channel W with interlace.

A similar program can perform a scatter-read operation. The difference is the exchange of the read instruction (RTD) with the write instruction (WTD) and the deletion of the file-protect testing instruction.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1000 | PZE |  | Saves a location for the subroutine entry. |
|  | CLR |  | Clears the A and B Registers. |
|  | STA | COUNT | Clears location COUNT for use later as a switch. |
|  | TRT | 0, 1 | Tests whether Magnetic Tape 1 on Channel W is Ready. |
|  | BRU | \$+2 | Branches two locations ahead. The computer executes it if the magnetic tape unit is Ready. |
|  | BRU | \$-2 | Branches back to the Ready test. |
|  | FPT | 0,1 | Tests whether the file-protect ring is present on the tape reel. If so, the computer skips the next instruction and executes the following one. The octal configuration is 04014011. |
|  | BRM | OPER | Branches and marks to an assumed routine to call the operator and instruct him to insert file-protect ring on Magnetic Tape 1. |
|  | LDA | 1000 | These three instructions place the marked subroutine entry |
|  | STA | FAST | location plus one into location FAST. |
|  | MIN | FAST |  |
|  | WTD | 0, 1, 4 | Connects Magnetic Tape 1 to Channel W, specifies BCD transfer mode and four characters per word, and starts the tape moving. The octal configuration is 00202651. |
|  | BRU | FAST + 1 | Branches around location FAST. |
| FAST | PZE |  | Saves a location for entry to the multiple write area of the subroutine. |
|  | LDX | COUNT | Loads the Index Register with the contents of COUNT, which picks up the proper input/output control instructions. |
|  | $\begin{aligned} & \text { LDA } \\ & \text { LDB } \end{aligned}$ | OKAY <br> MASK | These five instructions determine when the write operation is complete. When it is, location COUNT contains the num- |
|  | SKM | COUNT | ber 6 and the active interrupt, level 31, is cleared. Loca- |
|  | BRU | $\$+2$ | $t$ ion MASK contains $77777777_{8}$. |
|  | BRU | * FAST |  |
|  | ALC | 0 | Alerts the interlace in Channel W for subsequent loading. |
|  | EXU | A, 2 | Executes the EOM located in address A modified by the Index. |
|  | POT | $A+1,2$ | Transmits to the channel the word count and starting address. |
|  | MIN | COUNT | These instructions add two to the contents of COUNT. |
|  | MIN | COUNT |  |
|  | BRU | * FAST | Branches back to the main program. |

The main program continues while the channel performs the output. When finished, the Zero Word Count interrupt goes to interrupt location 31.

| Location Instruction | Address | Comments |  |
| :--- | :--- | :--- | :--- |
| 31 | BRM | FAST | Branches and marks at location FAST. |

The routine repeats this for the output words in $A+2$ and in $A+4$. Then the test in location FAST +4 causes a final Branch to clear interrupt (BRU) back to the main program.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| A | $\begin{aligned} & \text { EOM } \\ & 06203720 \end{aligned}$ | 15600 | This EOM specifies terminal output function 11 (IOSP) and the Count Equals Zero interrupt. The word in A +1 specifies that 100 words will be read out from memory beginning in location 2000. |
| A + 2 | $\begin{aligned} & \text { EOM } \\ & 14404740 \end{aligned}$ | 15600 | This EOM specifies terminal output function 11 (IOSP) and the Count Equals Zero interrupt. The word in $\mathrm{A}+3$ specifies 200 words from memory beginning in location 2500. |
| A + 4 | $\begin{aligned} & \text { EOM } \\ & 06205670 \end{aligned}$ | 15000 | The EOM specifies terminal output function 00 (IORD) and the Count Equals Zero interrupt. The word in $\mathrm{A}+5$ specifies 100 words from memory beginning in location 3000. Upon completion of the output of this sub-record, the channel disconnects. |
| OKAY | 00000006 |  | This is the stored number 6 used in the completion test above. |

NOTE: This sample program is for clarification of magnetic tape programming. It does not include extra programming to save the contents of the $A$ or the Index Register for the main program.

## LINE PRINTER

XDS buffered line printers are capable of printing up to 1000 lines per minute at 132 characters per line, with a standard set of 56 characters. Printing is accomplished by means of a rotating character drum and a bank of 132 print hammers. The drum passes 56 different characters, in lines of 132 each, past the hammer bank. Upon command from the computer, the selected print hammers drive the paper against the ribbon and onto the appropriate character typeface as it passes the print position. The characters are transmitted sequentially for storage in the printer buffer before printing. A programmable format tape loop provides fixed (or preselected) space control. Upspacing of 1 to 7 lines, as well as page control, may be accomplished by program instructions.

An optional, off-line facility allows the program or the operator to initiate card-to-printer or magnetic tape-to-printer operations simultaneous with computation (see Off-Line Printing).

## Printer Controls

The printer controls, Figure 4-5, for XDS line printers consist of eight switches and indicators.

Figure 4-5. Printer Control Indicator Lights and Switches
The POWER/ON switch is an alternate action switch. The computer must be turned on for this switch to be activated. Pressing POWER/ON lights the top half of the indicator, turns on the motors and hammer driver power supply, and starts a timer that allows the motors to reach proper speed. After 20 seconds the bottom half lights, indicating that the printer is operable.

When the printer is initially turned on, the READY indicator is off. When pressed, it is turned on if:

1. paper is loaded in the line printer,
2. the lower half of the POWER/ON switch is lighted, and
3. the hammer power supply is on.

This indicator automatically goes off when the above conditions are not realized. The printer is ready for either online or off-line operation when READY is turned on. Ready is reset to preclude computer intervention while changing paper or ribbon, or operating the TOP OF FORM or SINGLE SPACE switches.

Pressing TOP OF FORM causes the printer to position paper according to format tape channel 1. This indicator is lighted only when the format tape is positioned at channel 1, that is, top-of-form on a standard tape loop. This switch is operative when there is paper in the printer and the READY indicator is off.

Pressing SINGLE SPACE causes the printer to upspace paper one single space, independently of the vertical format tape. This switch is operative when there is paper in the machine and READY is off.

The FAULT indicator lights when the printer detects a parity error as information transfer from the buffer to the print hammers, or when it detects a parity error in incoming data from magnetic tape or cards during an off-line operation. It remains lighted until the next EOM addresses the printer. The condition of the light corresponds to the status of a program-testable fault indicator in the printer.

MANUAL/OFF LINE ${ }^{\dagger}$ is a combination of a switch and two independent indicators. The program or the operator may initiate off-line operation, which is indicated by the illumination of OFF LINE (the bottom half of this switch). If the operator presses this switch to initiate off-line operation, MANUAL (the top half of the switch) is also lighted and remains lighted until the operator presses the switch again. OFF LINE is normally reset when the end-of-file is detected from the input unit. Pressing READY also resets OFF LINE, that is, by switching the printer from the "ready" to the "not ready" state.

The FORMAT/SPACE ${ }^{\dagger}$ switch is used in off-line operation. The operator may use either mode, spacing a single space after each line of print, or using the first character stored on tape or cards as a vertical format character.

The TAPE/CARD ${ }^{\dagger}$ switch selects the desired input device.

Paper Tape Format Loop
A paper tape format loop, placed in the printer, allows upspacing to proceed to prespecified vertical positions on the print page. The format loop is an eight-channel paper tape. Putting a punch in the specified channel at the desired vertical spacing selects the channel upspace. Channel lis the top-ofform channel, channel 7 is the bottom-of-form channel, and channel 0 is the single-upspace channel. In the off-line mode with SPACE control, channel 0 controls single spacing. When printing with no format loop inserted in the printer, single upspacing occurs regardless of the channel specified.

[^1]
## Line Printer Instructions

## PLP 0,1,4 PRINT LINE PRINTER

00202660
This instruction connects the line printer to channel $W$ and specifies a character transmission of 4 characters per word.

This instruction is followed by the transmission of up to 132 characters. If the character count is less than 132, the characters are printed left-justified on the page. If the character count is more than 132, the printer produces an undetectable error.

The following control instructions are coded for Channel W using unit number 1 :

## POL 0, 1 PRINTER OFF-LINE <br> 00210260

This instruction places the printer off-line and initiates an offline print operation. The selected input device (card reader 1 or magnetic tape unit 7) also goes off-line (See Off-Line Printing).

## PSC 0,1,n PRINTER SKIP TO FORMAT $002 \ln 460$ CHANNEL n

This instruction causes the printer to eject paper until the paper tape format loop detects the first punched hole in the channel specified by the number $n$ ( 0 to 7 ). (See PSP for timing.)

PSP 0, 1,n PRINTER UPSPACE n LINES $002 \ln 660$
This instruction causes the printer to upspace $n(0$ to 7 ) lines. Consecutive upspace instructions must be separated by a sufficient time delay. Otherwise, the two PSP instructions may be merged by the printer.

Approximate completion times for PSP (from initiation of instruction to paper stop) are:

Upspace 1 line: 25 milliseconds (14, 275 cycles)
Upspace more than 1 line: add 10 milliseconds ( 5,690 cycles) for each additional line.

## Line Printer Tests

The line printer tests to follow are coded for channel W using unit number 1 :

## PFT 0, 1 PRINTER FAULT TEST <br> 04011060

(Skip if no Printer Fault)

This test determines if the printer has detected a parity error during a transfer of information from the printer buffer to the print hammers. If such an error occurs, a fault detector is set and the FAULT indicator is lighted. If the fault detector is set when PFT is executed, the computer executes the next instruction in sequence (does not skip). If the fault detector is not set, the computer skips the next instruction in sequence and executes the following instruction.

```
PRT 0,1 PRINTER READY TEST
    (Skip if Printer Ready)
```

This instruction tests the printer for a "ready" condition. The criteria for a printer "ready" condition are:

1. Paper is loaded in the machine,
2. The lower half of the POWER/ON switch is lighted, and
3. The hammer power supply is on.

If the printer is ready when PRT is executed, the computer skips the next instruction in sequence and executes the following instruction. If the printer is not ready, the computer executes the next instruction in sequence (does not skip). Since the printer tests ready while ejecting paper, the program should allow a definite time interval to pass (see PSP) after a PSC or PSP instruction before executing a new PSC or PSP. A dummy PLP instruction may be issued between two space instructions (PSC or PSP). This instruction will provide the timing required. A ready test may be used to determine when the second paper space instruction may be sent.

## EPT 0, 1

## END OF PAGE TEST

04014060
(Skip if not End of Page)
This instruction tests the printer for paper position. If the paper is positioned at the end of page (specified by format channel 7) the computer executes the next instruction in sequence (does not skip). If the paper is not positioned at the specified end of page, the computer skips the next instruction in sequence and executes the following instruction.

## Terminating Line Printer Output

When the single-word mode of transmission is used for printing on the line printer, each character transmission for a line must be followed by a TERMINATE OUTPUT (TOP) instruction. TOP is automatically generated with interlaced outputs.

## Error Conditions

1. Print fault - parity error during transfer of character information from print buffer to print hammers.
2. Buffer error - parity of character rate error during transfer of information through buffer.
3. Input fault - parity error in incoming data from cards or magnetic tape (during off-line operation only).

## Off-Line Printing

The optional, off-line facility allows the line printer to produce printed records from card or magnetic tape sources without computer attention. The character transmission proceeds directly from the source to the printer and the channel may still be used by the computer for other input/output operations (e.g., card reading on card reader 2, card punch, paper tape read/punch, disk read/write, etc.). Once initiated, the printing operation is controlled by the source and proceeds until the source generates an end-of-file signal (see card input and magnetic tape input for appropriate end-of-file conditions).

The FAULT indicator lights when a parity error is detected during the reading of a tape record; the off-line printer rereads the record in an attempt to read good data. If this reread record contains an error, FAULT lights, the off-line operation terminates, and the printer goes back on-line if physically connected

EXAMPLE: Print Two Lines

This program positions the paper at the top of the page and prints two lines with a single upspace between them. It assumes that the printer is ready to print or is becoming ready after a print operation. This program, written as a closed subroutine, uses channel W, Line Printer 1, and the Count Equals Zero and End-of-Record interrupts.

| Location | Instruction | Address | Comments |
| :---: | :---: | :---: | :---: |
| 1200 | PZE |  | Reserves a location for subroutine entry. |
|  | CLR |  | Clears the $A$ and $B$ Registers. |
|  | STA | SWICH | Initializes a location, SWICH, which indicates that printing is completed. |
|  | PRT | 0,1 | Tests for printer ready. The octal configuration for this instruction is 04012060. |
|  | BRU | s-1 | Returns control to the ready test; if the printer is not ready, the computer executes this instruction. |
|  | PSC | 0,1,1 | Instructs the printer to move paper to the top of the page. The octal configuration for this instruction is 00211460 . |
|  | PLP | *0, 1,4 | Connects Printer I to Channel W, and specifies four characters per word transfer mode, and alerts the interlace. The octal configuration for this instruction is 00242660. |
|  | EXU | PRINT | Executes the EOM located in location PRINT. |
|  | POT | PRINT + 1 | Transmits the word count and starting address. |
|  | BRR | 1200 | Branches back to the main program while the line is being printed. |
| PRINT | $\begin{aligned} & \text { EOM } \\ & 02043720 \end{aligned}$ | 16200 | This EOM specifies output function 01 and the End-of-Record interrupt. The word in PRINT +1 specifies that 33 words will be output from memory beginning in location 2000. |

The main program continues while the data transfer and printing is being completed. When completed, the End-of-Record interrupt goes to interrupt level 33. This indicates that all the data from memory has been obtained, and that the printing of the line has been completed.

| 33 | BRM | UPSPC | Branches and marks to location UPSPC elsewhere in memory. |
| :---: | :---: | :---: | :---: |
| UPSPC | PZE |  | Reserves a location for an entry. |
|  | PRT | 0,1 | Tests for printer ready condition. Since the current line has been printed, the printer will be ready. |
|  | BRU | *-1 | Returns to the test. |
|  | PSP | 0, 1, 1 | Causes the printer to upspace one line. The octal configuration is 00211660. |
| HEAR | PLP | *0,1,4 | Sets up the printer with interlace. |
|  | EXU | PRNT | Executes the EOM in location PRNT. |
|  | POT | PRNT + 1 | Transmits to the channel the word count and starting address. |
|  | BRU | *UPSPC | Branches and clears the interrupt to the main program to await completion of the data transfer. |
| 31 | BRM | DONE | Branches and marks to location DONE elsewhere in memory. |
| DONE | PZE |  | This pseudo operation reserves a location for an entry. |
|  | MIN | SWICH | Sets the printing complete flag. |
|  | BRU | *DONE | Branches back to the main program and clears interrupt 31. This is the final exit. |
| PRNT | $\begin{aligned} & \text { EOM } \\ & 02043761 \end{aligned}$ | 15000 | This EOM specifies terminal output function 00(IORD) and the Count Equals Zero interrupt. The word in PRNT +1 specifies that 33 words will be read out from memory beginning in location 2033. The channel disconnects at the end of the output. |

At location HEAR, note that the computer executes the instructions to print and control the printing before the printing has had time to completely upspace the paper as requested. The instructions cause an immediate transfer of data into the Print Buffer and printing begins immediately after completion of upspacing.
to the computer and the MANUAL indictor is off. When a validity check occurs during a card read, FAULT lights, the operation terminates, and the printer goes back on-line if the MANUAL indicator is off. The next EOM addressing the printer resets FAULT if the printer is on-line. If the MANUAL indicator is on, the error condition may be cleared by pressing READY off and then on again. If a fault occurs in an off-line operation initiated by the computer, the usual method for clearing the error is:

1. Press MANUAL on.
2. Press READY off.
3. Press READY on.

## 4. Press MANUAL off.

In a manually initiated off-line operation, steps 1 and 4 are not required.

Off-line printing can be formatted as desired through the use of a single upspace or the format control mode (see Table 4-2). Off-line printing terminates by an end-of-file indicator from either device. Upon termination of an off-line operation, a physically connected off-line printer system returns on-line, provided the MANUAL indicator is off.

Table 4-2. Format Control Characters

| Code | Character | Function |
| :--- | :--- | :--- |
| 00 | 0 | Skip to format channel 0 |
| 01 | 1 | Skip to format channel 1 |
| 02 | 2 | Skip to format channel 2 |
| 03 | 3 | Skip to format channel 3 |
| 04 | 4 | Skip to format channel 4 |
| 05 | 5 | Skip to format channel 5 |
| 06 | 6 | Skip to format channel 6 |
| 07 | 7 | Skip to format channel 7 |
| 40 | - (hyphen) | Do not space |
| 41 | J | Upspace 1 line |
| 42 | K | Upspace 2 lines |
| 43 | L | Upspace 3 lines |
| 44 | M | Upspace 4 lines |
| 45 | N | Upspace 5 lines |
| 46 | O | Upspace 6 lines |
| 47 | P | Upspace 7 lines |

## Printing Off-Line Under Operator Control

The procedure for operator control of off-line printing is:

1. Switch on the desired input device. (Magnetic tape is selected by dialing it to logical tape number 7.)
2. Place paper at top of form, as desired, by means of the TOP OF FORM switch.
3. Select desired input device by means of the TAPE/CARD switch.
4. Select either the FORMAT or SPACE mode as required.
5. Press MANUAL/OFF LINEswitch.
6. Press READY switch on, which initiates actual data transfer.

## Printing Off-Line Under Computer Control

The procedure for computer control of off-line printing is:

1. Turn the equipment on.
2. Prepare the desired input device for operation.
3. Select desired input device by means of the TAPE/CARD switch.
4. Select either the FORMAT or SPACE mode as required.
5. Press the READY switch on.
6. Under program control, test the tape or card unit and the line printer for "ready" condition.
7. Then, to start transfer of data, give the POL instruction to print off-line.

## Off-Line Print Termination

Off-line printing terminates when an end-of-file indicator from the magnetic tape unit or card reader occurs. When printing from magnetic tape, the print operation terminates when the first character read from a record is the end-of-file code, octal 17.

When printing from cards, the print operation terminates when the end-of-file signal comes from the reader. This occurs when the card hopper becomes empty and the EOF ON switch on the reader is on (END OF FILE indicator lights). If the hopper becomes empty when EOF ON is not lighted, the printer waits for more cards to be placed in the hopper and the reader to become ready. When the reader is again ready, printing resumes.

## XDS CHARACTER CODES

| Characters |  |  |  | Magnetic Tape | Characters |  |  |  | Magnetic Tape BCD Code on Tape |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

|  | (5) | $37(2)$ |  |  | elete |  | $77 \text { (2) }$ | 0-8-7 | 37 |

NOTES:
(1) The characters ? ! and $\ddagger$ are for input only. The functions Backspace, Carriage Return, or Tab alwoys occur on output.
(2) On the off-line paper tape preparation unit, 37 serves as a stop code and 77 as a code delete.
(3) The internal code 12 is written on tape as a 12 in BCD . When read, this code is always converted to 00 .
(4) The codes 12-0 and 11-0 are generated by the card punch; however, the card reader will also accept 12-8-2 for 32 and 11-8-2 for 52 to maintain compatibility with earlier systems.
(5) For the 64-character printers only.

## TWO'S COMPLEMENT ARITHMETIC

XDS computer systems hold negative numbers in memory in binary two's complement form. The two's complement of a binary number is formed by adding one to the one's complement (logical inverse) of the number. This convention allows the sign of a number to be used as an integral part of the number in all arithmetic operations and obviates the need for keeping track of a detached sign with computer logic.

In XDS systems, the sign bit is in the first bit position to the left of the most significant magnitude bit. Thus, if an XDS computer word was only 6 bits long instead of 24 , some common decimal values would be represented in binary format as follows:

| Decimal <br> Number | Octal <br> Equivalent | Complement <br> Plus 1 | Binary <br> Equivalent |  |
| :---: | :---: | :---: | :---: | :--- |
|  |  |  |  |  |
| 3 | 03 | - | 000011 |  |
| 2 | 02 | - | 000010 |  |
| 1 | 01 | - | 000001 |  |
| 0 | 00 | - | 000000 |  |
| -1 | $(-) 01$ | 77 | 111111 |  |
| -2 | $(-) 02$ | 76 | 111110 |  |
| -3 | $(-) 03$ | 75 | 111101 |  |
| 31 | 37 | - | 01111 |  |
| -31 | $(-) 37$ | 41 | 100001 |  |

This table suggests the following algorithms:

1. To find the binary, two's complement of a negative decimal number:
a. Find the octal equivalent of the absolute of the number
b. Form the complement and add one
c. Express as a binary number.

The result is the binary, two's complement equivalent.
2. To find the decimal equivalent of a binary two's complement number:
a. Express as an octal number
b. Subtract one and form the complement
c. Find the decimal equivalent.

The negative of the result is the decimal equivalent.
The following examples show how two's complement numbers automatically yield the correct result when used arithmetically in the computer.

| Decimal <br> Number | Binary <br> +20 <br> -03 <br> +17 |
| :--- | :--- | | $\frac{\text { Equivalent }}{010100}$ |
| :--- |$\quad$| +111101 |
| :--- |
| Lost carry |

Note that the carry out of the most significant (sign bit) position is lost. Nevertheless, the value remaining is the correct answer.

| Decimal <br> Number | Binary <br> Equivalent |
| :--- | :--- |
| -32  <br> +24  <br> -8  | 100000 <br> 111000 |
|  | $(-) 10_{8}=-8$ |

When performing additions or subtractions in the computer, carries out of the sign bit do not always signify a true overflow condition or cause the OVERFLOW indicator to be set. In an addition, it is impossible to produce an overflow if the signs of the operands are unlike. The computer sets the OVERFLOW indicator in an addition only when the signs of the two operands are the same, but the sign of the result is opposite. In a subtraction, which in the computer is accomplished by forming the two's complement of the subtrahend and then adding to the minuend, the test for overflow is similar to that for addition. That is, overflow occurs when both numbers have the same sign after the subtrahend has been complemented but the sign of the result is opposite.

## OPTIONAL EQUIPMENT

## data multiplexing system

The standard I/O systems provided with the XDS 930 Computer provide for operation with all standard XDS peripheral equipments and for high-performance special devices. The Data Multiplexing System provides an alternate I/O system that is of particular use in dealing with multiple source of data and for systems which may have very high data rates (see Figure A-1).

The XDS 930 Computer has essentially two major paths along which I/O data can flow to and from memory. The first path is the same that is used by the main frame itself. The PIN/ POT operations use the first path. All Time-Multiplexed Communication Channels also use this path. In addition to this path, which is primarily under the control of the main frame, there is an optional second path that is completely under the control of the units attached to it. The second path has priority over the first for access to memory. This path is made available with the installation of the Multiple Access to Memory Feature.

## MULTIPLE ACCESS TO MEMORY FEATURE (MAM)

The Multiple Access feature provides the necessary modules on both main frame and memory to permit memories to be accessed via the second path. A word can be transferred over the path in either direction in one cycle. If the computer is equipped with two or more memories and the main frame is communicating with one memory while some other device is using the second path to another memory, then there is no interference with computation. If both the main frame and an I/O device using the second path address the same memory, the second path has priority; the program loses one cycle while the second path transmits.

The Multiple Access feature is required for the attachment of Direct Access Communication Channels (DACC), Data Multiplex Channels (DMC), or Memory Interface Connections (MIC). These devices all incorporate a priority scheme for determining the assignment of the second path. (See Figure A-1.) Only four DACCs can be attached to one computer system; Memory Interface Connections, and Data Multiplex Channels, however, are unlimited in number.

A practically unlimited number of MICs in addition to the four DACCs and the Data Multiplexing System (DMS) can be attached to a computer system. Each MIC has the necessary priority control to operate with other MICs and DACCs and the DMS. Both MICs and DACCs can be arranged so as to produce any required configuration of priorities.

## DATA MULTIPLEXING BASIC ELEMENTS

A Data Multiplexing System consists of two basic elements:

1. The Data Multiplex Channel (DMC) for communicating with several data sources/destinations and for synchronizing I/O operations with memory, MICs, DACCs, and other DMCs.
2. One or more Data Subchannels (DSC) for interfacing between peripheral devices and systems and the DMC.

## Data Multiplex Channel (DMC)

The Data Multiplex Channel is the basic unit for the Data Multiplexing System. It connects to the second path to memory via the Multiple Access to Memory feature. A DMC consists of 24-bit register and control logic. All addresses and data are transmitted between the DMC and subchannels via a bus system. The data and address are connected to memory via the MAM only when a transfer is to be made. All program control required for a given I/O operation operates directly on the individual subchannel, not the DMC.

The DMC is equipped with an internal interlace feature. This feature allows a subchannel to specify the address of a word in memory where the data address and count are to be found. When operating with internal interlace, the subchannel supplies the address of its interlace word instead of the actual data address. The DMC reads out the interlace word, increments the address portion, decrements the count, restores the word and then accepts the data from or transmits the data to the subchannel. The DMC also supplies a signal to the subchannel if the decremented count is zero.

The format of the internal interlace word or word pair is as shown:

The 9-bit word count allows for block lengths to 512 words. With the 930 , transmissions using internal interlace require 3 cycles per word.

The DMC also provides for automatic memory incrementing. The counting capability of the DMC register is such that the entire 24-bit register or either the upper 12 bits or the lower 12 bits may be incremented. When such a memory increment operation is to be performed, the subchannel signals the DMC with a special increment line and supplies the address. The DMC reads out the word, increments it and then restores. If the word was zero after the incrementing, the DMC signals the subchannel which may then interrupt the program. The maximum incrementing rate is 1 count every $2 \mathrm{cy}-$ cles. Parity generation and detection are available.

## Data Subchannels (DSC-N)

There are a number of subchannels which can be attached to the DMC. A full word, 24 bits plus parity, is available for the 930. Words (24 bits) are assembled in two 12-bit characters. Subchannels can control and generate program interrupts but do not include the interrupt levels themselves. The signals must be routed to optional interrupt levels if the interrupt features are to be used.

Figure A-1. XDS 930 Overall Computer Configuration

The subchannels use a priority scheme to determine which may transmit to the DMC at any given time. This is similar to the scheme used by the MICs, DMCs, and in transmitting to memory. Up to 128 DSCs can be connected to a DMC. A DSC can use the internal interlace feature of the DMC to control its transmission or it can be equipped with an external interlace (EIN).

A DSC using internal interlace has two words assigned to it. These two words are adjacent even/odd locations and are fixed for a given subchannel. The program can select either the even or odd location. If the even location is selected, the subchannel will automatically switch to the odd location when the count field of the even word is zero. The program can also select whether or not the subchannel will switch back to the even word when the count field of the odd word is zero. The subchannel will generate an interrupt signal when the count field of either word reaches zero. Transmission termination occurs when the odd word's count equals zero if the subchannel does not switch back to the even word.

The two-word internal interlace allows a subchannel to handle continuous data by alternately working from one memory area or another. By allowing the subchannel to switch automatically from one interlace word to the other, the program is relieved of the necessity for making real-time responses to the zero count condition. Using first the even then the odd interlace word allows maximum word count of 1024 for a pair of interlace words.

## CHARACTER SUBCHANNEL (DSC-I)

The DSC-I contains a 12-bit data register that can assemble and disassemble two 6-bit characters, and transmit one or two 6 -bit characters or one 12 -bit character. It checks and generates the parity of characters to enable it to couple with standard XDS peripherals. The DSC-I has a unit address register. For the 9300, it can be used for multiple typewriters or other character-oriented devices. However, it only uses 12 bits of the full 24-bit word.

The subchannel can operate with either internal or external interlace. It has one mode of output and two modes of input. During output, it transmits until the odd internal interlace word count is zero and then terminates if interlace cycling is not requested. The output can also be terminated if the device sends an END signal to the channel. This END signal may cause the DSC-I to generate an interrupt to the program.

Input, like output, can always be terminated due to an external END signal. The program can also specify if the DSC is to terminate and disconnect on zero count or disconnect only on the END signal. In either case, however, all transmission to memory is terminated after the odd interlace count reaches zero if interlace cycling is not requested.

## FULL-WORD SUBCHANNEL (DSC-II)

The DSC-II is a general purpose subchannel designed to allow communication with word-oriented input/output units such as analog-digital and digital-analog converters. It contains no storage for data. The external device must be capable of holding the data during the transmission to/from the DiMC. (An A-to-D converter would have such capability). Like the DSC-I, the DSC-Il can operate with either internal or external interlace.

Its operation in this respect is identical to that of the DSC-I. The DSC-II also contains control logic to facilitate memory increment operations in conjunction with the DMC.

## EXTERNAL INTERLACE

The external interlace (EIN) can be attached to the DSC to control the transmission of its data to/from memory. The EIN consists of a 15-bit address register and a 9-bit count register. These registers are loaded automatically when the subchannel is activated, the information coming from the internal interlace memory locations. Once the EIN is set up, it will contro! the transmissions of the DSC at a maximum rate of 1 word per memory cycle. After each word is transmitted, the EIN increments its address register and decrements its count. When the count equals zero, the EIN signals the DSC, which can then generate a program interrupt and/or notify the external device. Transmission normally terminates on zero count. Sequencing of interlace words is identical to the sequence of operation performed for internal interlace, except that only two memory cycles are used for interlace word processing. The first is to access the interlace word initially; the second is to restore the interlace word when the count reaches zero.

## PROGRAM CONTROL OF DATA SUBCHANNELS

Transmission of data between a DSC and computer memory is controlled by two 24 -bit interlace control words unique to the DSC and wired into fixed adjacent locations in memory. During a transmission the DMC/DSC uses the two interlace control words for determination of transmission address and record length.

The DSCs are numbered from 0 to 0376 in even octal numbers; this permits a maximum of 128 subchannels. The memory locations of the interlace control word pairs associated with the DSCs are numbered X0000, X0001 for DSC-0, X0002, X0003 for DSC-2 . . X0376, X0377 for DSC-376. DSC-I numbering need not be contiguous, but DSC-II's are configured one or two in a module and are numbered with adjacent numbers. If a system contains multiple DSC-II modules (each with 1 or 2 subchannels), the module numbering need not be contiguous; 4,0 and 0224,0220 and 0314 is a typical possibility for five DSC-II subchannels. Transmissions to and from the DSC and memory may be under internal interlace control or, when so equipped, under external interlace control.

## INTERNAL INTERLACE

During an internal interlace transmission, the DMC controls the interlacing operation in the following order:

## 1. Access Interlace Word

The DMC accesses the interlace word assigned to the requesting subchannel.
2. Process Interlace Word

The DMC increments the 15 -bit address portion of the word and decrements the 9-bit word count.
3. Test for Zero and Set Indicator

Next, the DMC tests the word count for zero and if it is zero, sets an indicator in the pertinent DSC.

## 4. Restore

The DMC then places the new word count/address values back into memory using the assigned address of requesting subchannel.
5. Access/Store as Requested

The DMC accesses or stores the transmitted word as requested using the incremental address (see above).
6. Stop or Continue

The DSC checks its zero count indicator and
a. if zero and working on the even interlace word, the DSC continues operation using the odd interlace word,
b. if zero, working on the odd interlace word and the cycle bit is set, the DSC continues using the even interlace word,
c. if zero, working on the odd interlace word and the cycle bit is reset, the DSC terminates the operation on a DSC-II or responds as required by the function control on a DSC-I.
d. if not zero, the DSC returns operation to the DMC to continue at 1 (above).

Note that the first address used is the "address specified plus one" and the first word count is the "word count specified minus one". In particular, an initial word count of zero causes a 512-word block to be transmitted.

## external interlace

During transmissions utilizing external interlace control, the interlacing operation proceeds as described above except that when the DSC is activated, the DSC with external interlace (EIN) requests the DMC to access the desired interlace control word. The interlace control word is sent to the EIN. Thereafter, data transmissions to and from the DSC to memory utilize the interlace address and word count supplied by the EIN.

Data transmissions using the EIN require only one cycle while those data transmissions using internal interlace require three cycles. Should a transmission result in the EIN detecting a zero word count condition, the DSC-EIN will restore the external interlace word and will proceed according to 6 (above). Any termination of a DSC operation prior to zero word count due to any externally derived halt signal also causes a restoring of the EIN interlace control word.

## DSC PROGRAMMING

An EOM, POT sequence selects, alerts, and controls the subchannel; an EOM, SKS sequence selects and tests the status and conditions of the subchannel.

The EOM has the form:

and is referred to as the "select EOM".

Bit positions 16-23 contain the DSC number being alerted; these numbers are the even numbers from 0 to 0376 for the DSC and the C field (bits 13,14 ) specifies one of three modes to which the DSC is alerted. When followed by a POT instruction, the modes have the following meaning:

## C Effect

Bit
Position

The subchannel decodes the lower 12 bits of the "POTted" word for controlling the interlace and interrupts. The control type EOM should precede the buffer control EOM.
For DSC-I the form is:

FC is a 2-bit function code similar to the TMCC/ DACC terminal function codes. The remaining bits function as described below for DSC-II.

For DSC-II, the form is:
The subchannel decodes the lower 12 bits (12-23) of the "POTted" word as the lower 12 bits of a buffer control mode EOM.

For DSC-I, this will select a device with the unit address field, set the character/word count, specify binary or $B C D$ format, forward or reverse, and leader or no leader.

For DSC-II, the 12 bits activate the subchannel and select the proper unit (if more than one is attached to the DSC).

The subchannel decodes the lower 12 bits of the "POTted" word as the lower 12 bits of an input/ output control mode EOM. If bits 18 through 23 are zero, the "POTted" word addresses the selected DSC.

For DSC-I, these bits perform such functions as rewind tape, space paper, etc.

For DSC-II, these bits perform such functions as required by the selected device attached to the DSC.

Function
A 1 in the EOR bit arms the End-of-Record interrupt for this channel.

A 1 in the ZWC bit arms the Zero Word Count interrupt.

Function
A 1 in the CY bit (cycle) sets the cycle mode such that the interlace will switch from the odd word back to the even word at the zeroing of the odd word count. If ZWC and CY are set, a zero count interrupt is generated each time the interlace switches (to either word - even or odd). If CY is set to 0 , the interlace will not proceed after the count of the odd word is zero; and a zero count interrupt occurs only when the count of the odd word is zero.

A 0 in the $E / O$ bit selects the even interlace word as the first insterlace word in a transmission; note that when starting on the even word, the interlace always switches to the odd word for further control when the even word count goes to zero. A 1 in $E / O$ sets the odd interlace word as the first interlace word in a transmission; the interlace ceases control when the odd word count reaches zero unless the $C$ bit is set to cycle.

## terminating dsc input/OUTPUT

Once the cycle bit has been set, the interlace continues to cycle back and forth between the even/odd interlace words. An EOM, POT sequence is used to terminate the cycle. The EOM is:

The lower 12 bits of the "POTted" word must be:

The interlace terminates the next time the count reaches zero in the odd interlace word.

For example, to terminate the cycle on DSC 4, use the following sequence:

EOM 071004
POT 010000

01000000000200
The SKS to test subchannels has the form:

| 0 | SKS | 7 | TEST | 0 | UNIT |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 023 |  | 89 | 1112 | 161718 | 23 |

A select EOM with $C$ equal to zero $(C=0)$ permits the $S K S$ to be directed to the subchannel or to the device attached to it. The UNIT field specifies the device to be tested; the TEST field is defined for the particular device.

When testing the subchannel, the UNIT field is set to 00 . The TEST field contains the same testing format as SKS for testing a TMCC.

For example, to test DSC 4 for error, use the following sequence:
EOM 070004
SKS 071000

## MEMORY INTERFACE CONNECTION

Once a computer is equipped with a multiple access to memory feature, one or more memory interface connections (MIC) can be attached. The MIC is a general interface between the computer and the outside world that allows special devices to be connected to the computer. The MIC converts between the 4 -volt logic levels used in the computer and the 8 volts used outside. It preserves the integrity of the memory by generating the parity of incoming data words. It will also check the parity of words read from memory to indicate memory failures. If incoming data is supplied with parity, the MIC will check for odd parity as it generates the internal memory parity and respond with a signal that indicates if the transmission was correct. The device that is connected to the MIC must store both the data and the address until the transmission to/from memory is completed.

## automatic power fail-safe system

The computer core memory holds its information with all power removed, but information in the computer registers is destroyed by loss of power. Upon failure of main power to the computer, this system provides that the contents of all registers and other volatile information are automatically stored in core memory; also, further writing into core storage is inhibited during the decay period of the computer de power supply ouiputs. Erroneous memory control is prevented during power-off and power-on operations. Power-off/-on interrupt routines permit proper resumption of a program, automatically, after power is restored. This solid-state system consists of ac power-sensing and memorysequencing circuitry, two high-priority interrupt channels, and a "shut-down/start-up" programming sequence.

The SKIP IF SIGNAL NOT SET (SKS) instruction is an aid in programming this option. Its address is 024000 . If the OFF interrupt (37) has just occurred, the computer executes the next instruction in sequence (does not skip).

## MEMORY PARITY INTERRUPTS

XDS computers incorporate an extensive memory parity checking system. The inclusion of parity generation and checking circuitry assures the integrity of data and instructions transferred among the memory, the central processing unit, and input/output channels.

In normal operation a switch on the computer console specifies the action to be performed by the computer when a memory parity error is detected. Two actions are available: the computer halts with the parity indicator lighted; or the computer ignores the parity error and proceeds with the program.

In many real-time applications it is desirable to keep the computer running when a parity error is detected. Also, the program must be notified of the error without stopping computation.

An optional feature provides this capability by means of two levels of enabled interrupts. One interrupt level is associated with the central processor; the other interrupt level with the Direct Access Communication Channels and the Data Multiplexing System. Memory parity errors detected from these two sources produce a priority interrupt associated with the cause. The processing routine associated with the interrupt can then take appropriate action, such as reinitiate the failed operation, notify the operator, or enter a diagnostic routine. Such action allows memory parity errors to be recognized and handled properly without hindering the computer's performance of real-time or on-line calculations.

## REAL-TIME CLOCK

The Real-Time Clock (RTC) provides a flexible time-orientation system for the XDS 930 Computer. It derives time pulses from the 60 -cycle computer power supply. These pulses are then used to produce a timing mark every 16.67 milliseconds, or optionally every 8.33 milliseconds. The Real-Time Clock can also accept timing marks from a customer-supplied input, thereby allowing time measurement to any required resolution for special applications. These timing marks are supplied at standard XDS logic levels to the computer's RTC circuitry.

The timing marks are then used by the computer and its interrupt system to provide either an elapsed-time counter or a continuously incrementing time counter depending on the needs of the customer. The RTC operates in either mode depending only on the computer's stored program.

| Location | Type | Computer | Description |
| :---: | :---: | :---: | :---: |
| 074 | Normal | 930 | CLOCK SYNC |
| 075 | Single Instruction | 930 | CLOCK PULSE |

The Clock Pulse and Clock Sync interrupts function together to provide elapsed-time, event counter, or time-of-day clocks.

The Clock Pulse interrupt is a single-instruction interrupt. (Note: See Single Instruction Interrupts in Section 3.) An MIN instruction is usually placed in the Clock Pulse interrupt location. When MIN is used as a single-instruction interrupt
subroutine, it causes the contents of the effective address to be incremented by one. Furthermore, if the new (incremented) contents of the effective address is 0000, a Clock Sync interrupt is generated. The Clock Sync interrupt can be generated in no other way.

## ELAPSED-TIME CLOCK

The elapsed-time clock times the length of a program or subroutine, or initiates or discontinues processing at programdetermined time intervals. An arbitrary memory location is reserved as a counter. When initialized, this cell contains the 2's complement of the number of time intervals to be counted. The Clock Pulse interrupt location contains an SKR instruction.

Each Clock Pulse interrupt results in decrementing the clock count by one. When the count is finished, an interrupt to the Clock Sync location occurs. A supervisory or other appropriate control program can then be entered to perform the customerdesired operation.

## CONTINUOUSLY INCREMENTING CLOCK

The continuously incrementing clock maintains "time-of-day" for the computer. One memory location serves to count the timing marks. In this case. the Clock Pulse is used to increment this location. (The Clock Pulse interrupt location contains an MIN instruction.) A simple, straightforward subroutine can be entered to reconstruct the exact time-of-day from this twenty-four bit count.

## ARM/DISARM

The Clock Pulse interrupt can be armed and disarmed with these instructions.

| EOM Effective Address | Action |
| :---: | :--- |
| 20200 | Disarm Clock Pulse <br> Interrupt |
| 20100 | Arm Clock Pulse Interrupt |

The Clock Sync interrupt is always armed.

## PROGRAMMED OPERATOR INSTRUCTIONS

The XDS Programmed Operator enables a programmer to code a subroutine call with a single instruction, just as if the subroutine were an actual machine instruction. Other computers usually perform standard subroutine calls by executing a transfer to the starting location of the subroutine and, at the same time, preserving a return address. This procedure requires an operation code (indicating a transfer) and an operand address (indicating the starting address of the subroutine). If the subroutine should require an additional operand, as in a floating point add subroutine, for example, the calling sequence must be longer to accommodate the specification of the operand.

The XDS Programmed Operator (abbreviated POP) uses the operation code to indicate the transfer address. When the computer detects a "one" in bit position 2 of an instruction, bit positions 2 through 8 are not interpreted as a normal instruction, but instead, are treated as an address to which the computer transfers control. Thus the operand address field is free to designate an address for use by the subroutine. There are 64 (decimal) locations $\left[(100)_{8}\right.$ through $\left.(177)_{8}\right]$ to which a transfer may occur. These 64 locations constitute a linkage table; they normally contain appropriate unconditional transfer instructions (BRU) to maintain the communication link between the POP code and the subroutine being called by it.

The location from which the transfer is made, at the time the computer detects the POP code (that is, the contents of the PRegister), is preserved in location 0. Thus the normal BRR instruction may be used to leave the POP subroutine and return to the main program. Also, the state of the overflow toggle is preserved in the sign bit position of location 0 and the overflow toggle is immediately reset.

To allow access to the operand in the main programby the POP subroutine, bit position 9 (the indirect address bit) is unconditionally set to "one". In this manner, when the subroutine refers indirectly to location 0 , the indirect addressing is perpetuated one more level, thereby enabling the subroutine to gain access to the operand in the main program. (See the Programmed Operator Example for further explanation.)

By judicious use of the programmed operator principle, a one-toone correspondence may be maintained between XDS 930 instructions and XDS 925 instructions. For example, XMA is a 930 machine instruction; its function may be simulated on the XDS 925 by a subroutine, and this subroutine may be called by means of a programmed operator. Thus, the main program requires the same number of instructions for either the XDS 925 or 930.

Another advantage of the programmed operator is the ability to change the arithmetic mode of a program without recoding the arithmetic portions of the program. For example, if the programmer codes all arithmetic instructions as programmed operators, he could simply change the arithmetic subroutine package and, hence, the arithmetic mode of the main program.

The following operations take place when the computer detects a programmed operator:

$$
\begin{aligned}
& \text { 1. } \quad(P) \rightarrow(0)_{10-23} \text {; save } P \text { Register for return address } \\
& \text { 2. } \quad 1 \longrightarrow(0)_{9} \quad \text {; insert indirect address bit } \\
& \text { 3. }\left(\mathrm{O}_{f}\right) \longrightarrow(0)_{s} \quad \text {; preserve status of overflow toggle } \\
& \text { 4. (C) })_{2-8} \rightarrow(P) \quad \text {; branch to location indicated in } \\
& \text { POP code }
\end{aligned}
$$

A library of programmed operator subroutines is available to greatly extend the XDS 930 instruction list. A list of these subroutines is given in this appendix. Each subroutine is specified by a unique mnemonic code and represents an available instruction which may be used directly in preparing 930 programs. Up to 64 of these programmed operator instructions may be used to prepare any one program.

The program loading system automatically organizes the interconnection between the programmed operator instructions and the corresponding subroutines. Each programmed operator instruction mnemonic code is converted on input to an instruction code of 1008 to 1778 . A memory location from $100_{8}$ through 1778 corresponding to each assigned instruction code is loaded with an unconditional branch to the corresponding subroutine.

XDS 930 PROGRAMMED OPERATOR EXAMPLE

| Location | Instruction |  |  | Effective <br> Address | Contents of Effective Address | Location 0 | $\mathrm{O}_{\mathrm{f}}$ | A Register | B Register |

Explanation: XMP is a programmed operator that produces the integer product of the integer in the A Register and the integer contained in the effective address. Overflow is set if the integer product exceeds the capacity of a single register. The contents of the $B$ and $X$ Registers are unaffected by this "instruction". In this example, $X M P$ is POP code 140 .

| Mnemonic | Description | Mnemonic | Description |
| :---: | :---: | :---: | :---: |
| LOG | Logarithm of A, single-precision, fixed-point | FLM | Floating multiply, double-precision |
| LGF | Logarithm of A, floating-point | FSM | Floating multiply, single-precision |
| EXP | Exponential of A, single-precision, fixed-point | FLD | Floating divide, double-precision |
| EXF | Exponential of A, floating-point | FSD | Floating divide, single-precision |
| ATN | Arctangent of A, single-precision, fixed-point | FLN | Floating negate, double-precision |
| ATD | Arctangent of $A$, double-precision, fixed-point | FSN | Floating negate, single-precision |
| ATF | Arctangent of A, floating-point | FSQ | Floating square root, double-precision |
| SIN | Sine of A, single-precision, fixed-point | SQR | Square root, single-precision, fixed-point |
| SND | Sine of A , double-precision, fixed-point | FFF | Fixed-floating format conversion |
| SNF | Sine of A, floating-point | LTP | Load, triple-precision |
| $\cos$ | Cosine of $A$, single-precision, fixed-point | LQP | Load, quadruple-precision |
| CSD | Cosine of A, double-precision, fixed-point | STP | Store, triple-precision |
| CSF | Cosine of $A$, floating-point | STQ | Store, quadruple-precision |
| DPA | Double-precision add | BDD | Binary to decimal conversion, double-precision, fixed-point |
| DPS | Double-precision subtract |  |  |
| DPM | Double-precision multiply | BFS | Binary to decimal conversion, single-precision, floating-point |
| DPD | Double-precision divide | BDF | Binary to decimal conversion, double-precision, floating-point |
| DPN | Double-precision negate |  |  |
| DSQ | Double-precision square root | DBD | Decimal to binary conversion, double-precision, fixed-point |
| LDP | Load double-precision | DFS | Decimal to binary conversion, single-precision, floating-point |
| STD | Store double-precision |  |  |
| FLA | Fioating add, double-precision | DBF | Decimal to binary conversion, double-precision, floating-point |
| FSA | Floating add, single-precision | BID | Binary to decimal conversion, single-precision, fixed-point |
| FLS | Floating subtract, double-precision |  |  |
| FSS | Floating subtract, single-precision | DIB | Decimal to binary conversion, single-precision, fixed-point |

## CHANNEL MEMORY ACCESS PRIORITY

During each memory cycle the control unit interrogates each channel to determine if it needs access to memory. If only one channel requires memory access, the control unit permits the channel to proceed immediately. If more than one channel requires memory access, the determination of which one proceeds first is on the basis of a fixed and a variable priority. The fixed priority is in the order: Direct Access Channel, Time-Multiplexed Channel, and Central Processor. Time-Multiplexed Channels have fixed priority in the order: D, C, Y, and W. Direct Access Channels have variable priority that is normally determined by comparison of the Word Assembly Register in each channel. The channel whose Word Assembly Register has the fewest number of characters remaining to be filled is selected for memory access. For example, if the Word Assembly Register in Channel E has one character position unfilled and the Word Assembly Register in Channel F has three character positions unfilled, Channel E is selected.

Thus, each channel increases its priority level as each character is read into the Word Assembly Register. If the contents of the register in two or more channels are equal in characters to be filled and no other channel in the set has fewer characters to be filled, priority is determined in sequence, with Channel E having top priority.

Note that the number of characters to be placed in the Word Assembly Register at any time is dependent on the characters per word count specified for the transmission. Consider, for example, that in Channel E the character count is three characters per word and in Channel F the character count is four characters per word. If both Channel F and Channel E need access to memory simultaneously, and if both have two characters filled in their respective Word Assembly Registers, then Channel E gets first memory access since it has only one character place to be filled.

## DIVISION INSTRUCTION

During execution of the DIVIDE (DIV) instruction, the contents of the A, B Registers taken as a double-precision number are divided by the single-precision contents of the effective address. If the numerator is a single-precision number, the program should clear the B Register prior to executing the DIV, or erroneous results may occur. Although a double-length numerator is used, DIV is a single-precision operation; it should not be confused with a double-precision divide operation that uses a double-length denominator and produces a double-length quotient.
After the execution of DIV, the single-precision quotient replaces the contents of the A Register, and the remaining portion of the numerator that has not been divided (undivided remainder) replaces the contents of the B Register. The quotient is signed in accordance with algebraic convention, that is, positive if numerator and denominator signs are alike, but negative otherwise. However, DIV generates only 23 magnitude bits and, if the magnitude of the quotient is so small as to require more than 23 bits to resolve, DIV may produce a zero quotient regardless of the required sign; but the remainder reflects the undivided portion of the original numerator. The binary scaling of the quotient is equal to the numerator scale factor minus the denominator scale factor.

The undivided remainder replaces the contents of the B Register and has the same sign as the original numerator. It is scaled, in $B$, at numerator scaling minus 23 . By definition, the undivided remainder is that quantity which must be added to the product of the denominator and the quotient to produce the original numerator. The results of the DIV instruction are consistent with definition. It should be noted that the program must shift the remainder right 23 places before adding it to the product of denominator and quotient to maintain proper scaling. Overflow is possible and the computer sets the Overflow Indicator if:
a) $\quad(A, B) /(M) \geq 1$
or
b) $\quad(\mathrm{A}, \mathrm{B}) /(\mathrm{M})<-1$

EXAMPLE:

Let | $(\mathrm{A}, \mathrm{B})$ | $=58.75 \mathrm{~B} 30$ |
| ---: | :--- |
| $(\mathrm{M})$ | $=10 \mathrm{~B} 8$ |

Binary scaling of the quotient $=30-8=22$
Binary scaling of the remainder $=30-23=7$
Complete quotient should be 5.875

With the binary scale point at 22 and only 23 bits generated in the quotient, the contents of A will be 5.5. In other words, only 55 of the original 58.75 units in the numerator are divided, leaving 3.75 units undivided. The undivided remainder is thus 3.75 B 7 in B .

## EXAMPLE:

Let | $(\mathrm{A}, \mathrm{B})$ | $=44.625 \mathrm{~B} 28$ |
| ---: | :--- |
| $\quad(M)$ | $=7 \mathrm{~B} 7$ |
| Quotient scaling | $=28-7=21$ |
| Remainder scaling | $=28-23=5$ |
| Complete quotient should be $44.625 / 7=6.375$ |  |

With the binary scale point at 21 , only 6.25 will be generated in A. Thus only $7 \times 6.25=43.75$ units are divided, leaving 44. 625-43.75=. 875 undivided. Therefore, the undivided remainder is . 875 B5 in B.
